Global Stability of Two-Group Epidemic Models
with Distributed Delays and Random Perturbation

We discuss a two-group SEIR epidemic model with distributed delays, incorporating random fluctuation around the endemic equilibrium. Our research shows that the endemic equilibrium of the model with distributed delays and random perturbation is stochastically asymptotically stable in the large. In addition, a sufficient stability condition is obtained by constructing suitable Lyapunov function.

1. Introduction

For the research of control of disease in populations, significant progress has been made in the theory and application of epidemiology modeling by mathematical research [1–8]. One of the main problems for the theory of differential equations and their applications is connected with stability. Most traditional compartmental models in mathematical epidemiology descend from the classical SIR model of Kermack and McKendrick [9], where the population is divided into the classes of susceptible, infected, and recovered individuals. For some diseases, such as influenza and tuberculosis, on adequate contact with an infectious individual, a susceptible becomes exposed for a while, that is, infected but not yet infectious. Thus it is realistic to introduce a latent compartment; the total population can be partitioned into four compartments: susceptible, latent or exposed, infectious, and recovered, with sizes denoted by S, E, I, and R, respectively. The resulting models are of SEI, SEIR, or SEIRS type, respectively. SEIR model has been widely discussed in the literature. Local and global stability analysis of the disease-free and endemic equilibria has been carried out using different assumptions and contact rates in [6, 7]. Greenhalgh [5] considered SEIR models that incorporate density dependence in the death rate. Korobeinikov [6] considers the global properties for SEIR and SEIS by means of the Lyapunov functions. In fact, there are real
benefits to be gained in using stochastic models because real life is full of randomness and stochasticity. Recently, some stochastic epidemic models have been studied by many authors, see [3, 10]. Dalal et al. [4] showed that stochastic models had nonnegative solutions and carried out analysis on the asymptotic stability of models. Tornatore et al. [10] studied the stability of disease-free equilibrium of a stochastic SIR model with or without distributed time delay. On the other hand, taking into account environmental variability, white noise stochastic perturbations around the positive endemic equilibrium of epidemic models was considered in [3, 11]. Beretta et al. proved the stability of epidemic model with stochastic time delays influenced by probability under certain conditions [3]. Such type of stochastic perturbations firstly was proposed in [3, 12] and later was successfully used in many other papers for many other different systems (see, for instance, [13–20]). A more general multigroup epidemic model is proposed to describe the disease spread in a heterogeneous host population with general age structure and varying infectivity by Li et al. [1]. They investigated a class of multigroup epidemic models with distributed delays and established the global dynamics determined by the basic reproduction number $R_0$. More specifically, they proved that, if $R_0 ≤ 1$, then the disease-free equilibrium is globally asymptotically stable; if $R_0 > 1$, then there exists a unique endemic equilibrium, and it is globally asymptotically stable. However, to the best of the authors’ knowledge, no literature exists regarding SEIR model with random perturbation. Thus, the current study hopes to serve such a need and is inspired by the report of [1]. In this paper, based on the SEIR model of [1], we consider the white noise stochastic perturbations around its endemic equilibrium and use the methods, which is similar to [3]. We construct a class of the Lyapunov functions, as it is useful to study the global properties of stochastic models. By means of it, we prove the SEIR model is stochastically asymptotically stable in the large under certain condition.

The paper is organized as follows. In Section 2 we recall the deterministic SEIR model and its main results by Li et al. [1]. We introduce the model with stochastic perturbations around the endemic equilibrium in Section 3. In Section 4 the global stability of the endemic equilibrium is proved by the method of the Lyapunov functions.

2. Preliminaries

We briefly review the following results obtained by Li et al. [1]. Let $S_k, E_k, I_k$, and $R_k$ denote the susceptible, infected but noninfectious, infectious, and recovered populations in the $k$th group, respectively. Let $i_k(t, r)$ denote the population of infectious individuals in the $k$th group with respect to the age of infection $r$ at time $t$, and $I_k(t) = \int_{0}^{\infty} i_k(t, r) dr$. Let $h_k(r) \geq 0$ be a continuous kernel function that represents the infectivity at the age of infection $r$. The disease incidence in the $k$-th group, assuming a bilinear incidence form, can be calculated as $\sum_{j=1}^{n} \beta_{kj} S_k(t) \int_{0}^{\infty} h_j(r) i_j(t, r) dr$, where the sum takes into account cross-infections from all groups and $\beta_{kj}$ represents the transmission coefficient between compartments $S_k$ and $I_j$. In the special case $h_k(r) \equiv 1$, the incidence becomes $\sum_{j=1}^{n} \beta_{kj} S_k(t) I_j(t)$ as in [2]. Therefore, the model in [2] can be generalized to the following system of differential equations

$$S_k = \Lambda_k - \sum_{j=1}^{n} \beta_{kj} S_k(t) \int_{0}^{\infty} h_j(r) i_j(t, r) dr - d_k^S S_k,$$

$$E'_k = \sum_{j=1}^{n} \beta_{kj} S_k(t) \int_{0}^{\infty} h_j(r) i_j(t, r) dr - \left( d_k^E + \epsilon_k \right) E_k,$$
\[ I'_k = e_k E_k - \left(d'_k + \gamma_k\right) I_k, \]
\[ R'_k = \gamma_k I_k - d^R_k R_k, \quad k = 1, 2, \ldots, n. \] (2.1)

Here \( \Lambda_k \) represents influx of individuals into the \( k \)-th group, \( d^S_k, d^E_k, d'_k, \) and \( d^R_k \) represent death rates of \( S, E, I, \) and \( R \) populations in the \( k \)-th group, respectively, \( e_k \) represents the rate of becoming infectious after a latent period in the \( k \)-th group, and \( \gamma_k \) represents the recovery rate of infectious individuals in the \( k \)-th group. All parameter values are assumed to be nonnegative and \( \Lambda_k, d^S_k, d^E_k > 0 \) for all \( k \). Note that

\[
\left( \frac{\partial}{\partial t} + \frac{\partial}{\partial r} \right) i_k(t, r) = -\left(d'_k + \gamma_k\right) i_k(t, r),
\]
\[
i_k(t, 0) = e_k E_k(t), \] (2.2)

whose solution is

\[
i_k(t, r) = i_k(t - r, 0)e^{-(d'_k + \gamma_k)r} = e_k E_k(t - r)e^{-(d'_k + \gamma_k)r}. \] (2.3)

Substituting (2.3) into (2), we obtain

\[ S'_k = \Lambda_k - \sum_{j=1}^{n} \beta_{kj} S_k(t) \int_{r=0}^{\infty} h_j(r)e_j E_j(t - r)e^{-(d'_k + \gamma_k)r} dr - d^S_k S_k, \]
\[ E'_k = \sum_{j=1}^{n} \beta_{kj} S_k(t) \int_{r=0}^{\infty} h_j(r)e_j E_j(t - r)e^{-(d'_k + \gamma_k)r} dr - \left(d^E_k + e_k\right) E_k, \]
\[ I'_k = e_k E_k - \left(d'_k + \gamma_k\right) I_k, \]
\[ R'_k = \gamma_k I_k - d^R_k R_k, \quad k = 1, 2, \ldots, n. \] (2.4)

Since the variables \( I_k \) and \( R_k \) do not appear in the first two equations of (2.4), Li et al. consider the following reduced system with distributed time delays and general kernel functions [1]:

\[ S'_k = \Lambda_k - \sum_{j=1}^{n} \beta_{kj} S_k(t) \int_{r=0}^{\infty} f_j(r) E_j(t - r) dr - d^S_k S_k, \]
\[ E'_k = \sum_{j=1}^{n} \beta_{kj} S_k(t) \int_{r=0}^{\infty} f_j(r) E_j(t - r) dr - \left(d^E_k + e_k\right) E_k. \] (2.5)

Here the kernel function \( f_k(r) \geq 0 \) is continuous and \( 1 \geq \int_{r=0}^{\infty} f_k(r) dr = h_k > 0 \). System (2.5) can be interpreted as a multigroup model for an infectious disease whose latent period
where $\lambda_k$ in hosts has a general probability density function $(1/h_k) f_k(r) \, dr$, for the $k$-th group. Let $S_k^0 = \Lambda_k / d_k^S, h_k = \int_{r=0}^{\infty} f_k(r) \, dr$. The next-generation matrix for system (2.5) is

$$M_0 = \frac{\beta_k S_k^0 h_k}{d_k^E + e_k}.$$  \hspace{1cm} (2.6)

Define the basic reproduction number as the spectral radius of $M_0$,

$$R_0 = \rho(M_0).$$  \hspace{1cm} (2.7)

In the special case when $f_k(r)$ is an exponential function, $R_0$ reduces to that for the resulting ODE models. Make the following assumption on the kernel function $f_k(r)$ in (2.5):

$$\int_{r=0}^{\infty} f_k(r) e^{-\lambda_k r} \, dr < \infty,$$

where $\lambda_k$ is a positive number, $k = 1, 2, \ldots, n$. Define the following Banach space of fading memory type:

$$C_k = \left\{ \phi \in ((-\infty, 0], \mathbb{R}) | \phi(s) e^{\lambda_k s} \text{ is uniformly continuous on } (-\infty, 0] \text{ and } \sup_{s \leq 0} |\phi(s)| e^{\lambda_k s} < \infty \right\}$$

with norm $\|\phi\|_k = \sup_{s \leq 0} |\phi(s)| e^{\lambda_k s}$. For $\phi \in C_k$, let $\phi_t \in C_k$ be such that $\phi_t(s) = \phi(t + s), s \in (-\infty, 0]$. Let $S_{k,0} \in \mathbb{R}_+$ and $\phi_k \in C_k$ such that $\phi_k(s) \geq 0, s \in (-\infty, 0]$. We consider solutions $(S_1(t), E_{1t}, S_2(t), E_{2t}, \ldots, S_n(t), E_{nt})$ of system (2.5) with initial conditions

$$S_k(0) = S_{k,0}, \quad E_k(0) = \phi_k, \quad k = 1, 2, \ldots, n.$$  \hspace{1cm} (2.10)

Standard theory of functional differential equations implies $E_{kt} \in C_k$ for $t > 0$. We consider system (2.5) in the phase space

$$X = \prod_{k=1}^{n} (\mathbb{R} \times C_k).$$  \hspace{1cm} (2.11)

It can be verified that solutions of (2.5) in $X$ initial conditions (2.10) remain nonnegative. In particular, $S_k(t) > 0$ for $t > 0$. The following set is positively invariant for system (2.5):

$$\Theta = \left\{ (S_1, E_2(\cdot), S_2, E_2(\cdot), \ldots, S_n, E_n(\cdot)) \in X \mid 0 \leq S_k \leq \frac{\Lambda_k}{d_k^S}, 0 \leq S_k + E_k(0) \leq \frac{\Lambda_k}{d_k^E}, E_k(s) \geq 0, \right. \left. s \in (-\infty, 0], k = 1, 2, \ldots, n \right\}.$$  \hspace{1cm} (2.12)
All positive semi-orbits in $\Theta$ are precompact in $X$ and thus have nonempty $\omega$-limit sets. We have the following results [1].

**Lemma 2.1.** All positive semi-orbits in $\Theta$ have non-empty $\omega$-limit sets. Let

$$
\Theta^o = \left\{ (S_1,E_2,\ldots,S_n,E_n) \in X \mid 0 < S_k < \frac{\Lambda_k}{d_k}, 0 < S_k + E_k(0) < \frac{\Lambda_k}{d_k}, E_k(s) > 0, \right\}
$$

$$
s \in (-\infty,0], k = 1,2,\ldots,n \right\}.
$$

(2.13)

It can be shown that $\Theta^o$ is the interior of $\Theta$.

**Lemma 2.2.** Assume that $B = (\beta_{kj})$ is irreducible.

(1) If $R_0 \leq 1$, then $P_0$ is the only equilibrium for system (2.5) in $\Theta$.

(2) If $R_0 > 1$, then there exist two equilibria for system (2.5) in $\Theta$: the disease-free equilibrium $P_0$ and a unique endemic equilibrium $P^*$.

**Lemma 2.3.** Assume that $B = (\beta_{kj})$ is irreducible.

(1) If $R_0 \leq 1$, then the disease-free equilibrium $P_0$ of system (2.5) is globally asymptotically stable in $\Theta$. If $R_0 > 1$, then $P_0$ is unstable.

(2) If $R_0 > 1$, then the endemic equilibrium $P^*$ of system (2.5) is globally asymptotically stable in $\Theta^o$.

Biologically, Lemma 2.3 implies that if the basic reproduction number $R_0 \leq 1$, then the disease always dies out from all groups; if $R_0 > 1$, then the disease always persists in all groups at the unique endemic equilibrium level, irrespective of the initial conditions.

### 3. Stochastic Model Derivation

In this paper, based on system (2.5), we consider the case of $k = 1,2$ in the following system (3.1):

$$
\dot{S}_k = \Lambda_k - \sum_{j=1}^2 \beta_{kj} S_k \int_{r=0}^\infty f_j(r)E_j(t-r)dr - d_k^S S_k,
$$

$$
\dot{E}_k = \sum_{j=1}^2 \beta_{kj} S_k \int_{r=0}^\infty f_j(r)E_j(t-r)dr - \left( d_k^E + \epsilon_k \right) E_k,
$$

$$
\dot{I}_k = \epsilon_k E_k - \left( d_k^I + \gamma_k \right) I_k,
$$

$$
\dot{R}_k = \gamma_k I_k - d_k^R R_k.
$$

(3.1)
It is easy to see that equilibrium for system (3.1) is given by \( P^* = (S^*; E^*; I^*; R^*) \),

\[
S_k^* = \frac{d_k^E + \epsilon_k}{\sum_{j=1}^{2} \beta_{kj} h_j}, \\
E_k^* = \frac{\Lambda_k - d_k^S}{\sum_{j=1}^{2} \beta_{kj} S_k^* h_j}, \\
I_k^* = \frac{\epsilon_k E_k^*}{d_k^I + \gamma_k}, \\
R_k^* = \frac{\gamma_k I_k^*}{d_k^R}.
\]  

(3.2)

We assume stochastic perturbations are of white noise type, which are directly proportional to distances \( S_k(t), E_k(t), I_k(t), R_k(t) \) from values of \( S_k^*, E_k^*, I_k^*, R_k^* \), influence the \( S_k(t), E_k(t), I_k(t), R_k(t) \) respectively. So system (2.4) results in

\[
\begin{align*}
\dot{S}_k &= \Lambda_k - \sum_{j=1}^{2} \beta_{kj} S_k \int_{r=0}^{\infty} f_j(r) E_j(t-r) dr - d_k^S S_k + \sigma_{1k} (S_k - S_k^*) B_{1k}, \\
\dot{E}_k &= \sum_{j=1}^{2} \beta_{kj} S_k \int_{r=0}^{\infty} f_j(r) E_j(t-r) dr - \left( d_k^E + \epsilon_k \right) E_k + \sigma_{2k} (E_k - E_k^*) B_{2k}, \\
\dot{I}_k &= \epsilon_k E_k - \left( d_k^I + \gamma_k \right) I_k + \sigma_{3k} (I_k - I_k^*) B_{3k}, \\
\dot{R}_k &= \gamma_k I_k - d_k^R R_k + \sigma_{4k} (R_k - R_k^*) B_{4k},
\end{align*}
\]  

(3.3)

where \( B_{1k}(t), B_{2k}(t), B_{3k}(t), B_{4k}(t) \) are independent standard Brownian motions and \( \sigma_{ik}^2 > 0 \) represent the intensities of \( B_{ik}(t) \) (i = 1, 2, 3, 4), respectively. Obviously, stochastic system (3.3) has the same equilibrium points as system (3.1). In the next section, we will investigate the stability of the equilibrium \( P^* \) of system (3.3). Below we will construct a class of different Lyapunov functions to achieve our proof under certain conditions.

**4. Stochastic Stability of the Endemic Equilibrium**

In this paper, unless otherwise specified, let \( (\Omega, \mathcal{F}, \{ \mathcal{F}_t \}_{t \geq 0}, P) \) be a complete probability space with a filtration \( \{ \mathcal{F}_t \}_{t \geq 0} \) satisfying the usual conditions (i.e., it is increasing and right continuous while \( \mathcal{F}_0 \) contains all P-null sets). Let \( \beta_i(t) \) be the Brownian motions defined on this probability space. If \( R_0 > 1 \), then the stochastic system (3.3) can be centered at its endemic equilibrium \( P^* = (S_k^*, E_k^*, I_k^*, R_k^*) \), by the change of variables

\[
u_k = E_k - E_k^*, \\
w_k = I_k - I_k^*, \\
z_k = R_k - R_k^*.
\]  

(4.1)

we obtain

\[
\begin{align*}
\dot{u}_k &= -\sum_{j=1}^{2} \beta_{kj} u_k \int_{r=0}^{\infty} f_j(r) v_j(t-r) dr - \sum_{j=1}^{2} \beta_{kj} S_k^* \int_{r=0}^{\infty} f_j(r) v_j(t-r) dr - \sum_{j=1}^{2} \beta_{kj} u_k E_j^* h_j - d_k^E u_k \\
+ \sigma_{1k} u_k B_{1k}, \\
\dot{v}_k &= \sum_{j=1}^{2} \beta_{kj} u_k \int_{r=0}^{\infty} f_j(r) v_j(t-r) dr + \sum_{j=1}^{2} \beta_{kj} S_k^* \int_{r=0}^{\infty} f_j(r) v_j(t-r) dr + \sum_{j=1}^{2} \beta_{kj} u_k E_j^* h_j \\
- \left( d_k^E + \epsilon_k \right) v_k + \sigma_{2k} v_k B_{2k},
\end{align*}
\]
\[ \dot{w}_k = \epsilon_k v_k - \left( d_k^l + \gamma_k \right) w_k + \sigma_{3k} w_k B_{3k}, \]
\[ \dot{z}_k = \gamma_k w_k - d_k^R z_k + \sigma_{4k} z_k B_{4k}, \quad k = 1, 2. \]

(4.2)

It is easy to see that the stability of the equilibrium of the system (3.3) is equivalent to the stability of zero solution of system (4.2). Before proving the main theorem we put forward a lemma in [21]. Consider the \( d \)-dimensional stochastic differential equation

\[ dx(t) = f(x(t), t)dt + g(x(t), t)dB(t), \quad t \geq t_0. \]

(4.3)

Assume that the assumptions of the existence-and-uniqueness theorem are fulfilled. Hence, for any given initial value \( x(t_0) = x_0 \in \mathbb{R}^d \), (4.3) has a unique global solution that is denoted by \( x(t; t_0, x_0) \). Assume furthermore that \( f(0, t) = 0 \) and \( g(0, t) = 0 \) for all \( t \geq t_0 \). So (4.3) has the solution \( x(t) \equiv 0 \) corresponding to the initial value \( x(t_0) = 0 \). This solution is called the trivial solution or equilibrium position. Denote by \( C^{1,1}(\mathbb{R}^d \times [t_0, \infty); \mathbb{R}_+) \) the family of all nonnegative functions \( V(x, t) \) defined on \( \mathbb{R}^d \times [t_0, \infty) \) such that they are continuously twice differentiable in \( x \) and once in \( t \). Define the differential operator \( L \) associated with (4.3) by

\[ L = \frac{\partial}{\partial t} + \sum_{i=1}^{d} f_i(x, t) \frac{\partial}{\partial x_i} + \frac{1}{2} \sum_{i,j=1}^{d} \left[ g^T(x, t) g(x, t) \right]_{ij} \frac{\partial^2}{\partial x_i \partial x_j}. \]

(4.4)

If \( L \) acts on a function \( V \in C^{1,1}(\mathbb{R}^d \times [t_0, \infty); \mathbb{R}_+) \), then

\[ LV(x, t) = V_t(x, t) + V_i(x, t) f_i(x, t) + \frac{1}{2} \text{Tr} \left[ g^T(x, t) V_{xx}(x, t) g(x, t) \right]. \]

(4.5)

Definition 4.1. (1) The trivial solution of (4.3) is said to be stochastically stable or stable in probability if for every pair of \( \epsilon \in (0, 1) \) and \( r > 0 \), there exists a \( \delta = \delta(\epsilon, r, t_0) > 0 \) such that

\[ P\{ |x(t; t_0, x_0)| < r \ \forall \ t \geq t_0 \} \geq 1 - \epsilon \]

(4.6)

whenever \( |x_0| < \delta \). Otherwise, it is said to be stochastically unstable.

(2) The trivial solution is said to be stochastically asymptotically stable if it is stochastically stable, and, moreover, for every \( \epsilon \in (0, 1) \), there exists a \( \delta_0 = \delta_0(\epsilon, t_0) > 0 \) such that

\[ P\left\{ \lim_{t \to \infty} x(t; t_0, x_0) = 0 \right\} \geq 1 - \epsilon \]

(4.7)

whenever \( |x_0| < \delta_0 \).

(3) The trivial solution is said to be stochastically asymptotically stable in the large if it is stochastically asymptotically stable and, moreover, for all \( x_0 \in \mathbb{R}^d \),

\[ P\left\{ \lim_{t \to \infty} x(t; t_0, x_0) = 0 \right\} = 1. \]

(4.8)
Lemma 4.2 (see [21]). If there exists a positive-definite decrescent radially unbounded function $V(x,t) \in C^{2,1}(R^d \times [t_0,\infty); R_+)$ such that $LV(x,t)$ is negative definite, then the trivial solution of (4.3) is stochastically asymptotically stable in the large.

From the above lemma, we can obtain the stochastically asymptotically stability of equilibrium as follows.

Theorem 4.3. Assume that $B = (\beta_{kj})$ is irreducible and $R_0 > 1$; then, if the following condition is satisfied

$$
\sigma^2_{1k} < 2d_k^E, \quad \sigma^2_{2k} < 2\left(d_k^E + \epsilon_k\right), \quad \sigma^2_{3k} < 2\left(d_k^I + \gamma_k\right), \quad \sigma^2_{4k} < 2d_k^R
$$

the endemic equilibrium $P^*$ of system (3.3) is stochastically asymptotically stable in the large.

Proof. It is easy to see that we only need to prove the zero solution of (4.2) is stochastically asymptotically stable in the large. Let $x(t) = (u(t), v(t), w(t), z(t))^T$. We define the Lyapunov function $V(x(t))$ as follows:

$$
V(x) = 2 \left\{ \sum_{k=1}^{2} \left[ a_k u_k^2 + v_k^2 + b_k (u_k + v_k)^2 + a_k^2 w_k^2 + a_k^2 z_k^2 + \sum_{j=1}^{2} \beta_{kj} S_k^* (1 + a_k) \int_{t-r}^{t} f_j(r) \left( \int_{t-r}^{t} v_j^2(\tau) d\tau \right) dr \right] \right\},
$$

where $a_k > 0, b_k > 0$ are real positive constants to be chosen later. So it is obvious that $V(x)$ is positive definite and decrescent.

Using Itô’s formula, we compute

$$
LV = \sum_{k=1}^{2} \left\{ 2(a_k u_k + b_k (u_k + v_k)) \right. \\
\times \left[ -\sum_{j=1}^{2} \beta_{kj} u_k \int_{t-r}^{t} f_j(r) v_j(t-r) dr - \sum_{j=1}^{2} \beta_{kj} v_k \int_{t-r}^{t} f_j(r) v_j(t-r) dr - \sum_{j=1}^{2} \beta_{kj} E_j^* h_j - d_k^E u_k \right] \\
+ 2(v_k + b_k (u_k + v_k)) \left[ \sum_{j=1}^{2} \beta_{kj} u_k \int_{t-r}^{t} f_j(r) v_j(t-r) dr + \sum_{j=1}^{2} \beta_{kj} E_j^* h_j - \left( d_k^E + \epsilon_k \right)v_k \right] \\
+ 2a_k^2 w_k \left( \epsilon_k v_k - \left( d_k^I + \gamma_k \right) w_k \right) + 2a_k^2 z_k \left( \gamma_k w_k - d_k^R z_k \right) + (a_k + b_k) \sigma_{1k}^2 u_k^2 + (1 + b_k) \sigma_{2k}^2 v_k^2 \\
+ a_k^2 \sigma_{3k}^2 w_k^2 + a_k^2 \sigma_{4k}^2 z_k^2 + \sum_{j=1}^{2} \beta_{kj} S_k^* (1 + a_k) h_j d_j^* - \sum_{j=1}^{2} \beta_{kj} S_k^* (1 + a_k) \int_{t-r}^{t} f_j(r) v_j^2(t-r) dr \right\}.
$$

(4.11)
Using (3.2), we obtain

\[
LV = \sum_{k=1}^{2} \left\{ -u_k^2 \left[ (a_k + b_k) \left( 2d_k^2 - \sigma_{ik}^2 \right) + 2 \sum_{j=1}^{2} a_k \beta_{kj} E_j^* h_j \right] - v_k^2 \left[ (1 + b_k) \left( 2 \sum_{j=1}^{2} \beta_{kj} S_k^* h_j - \sigma_{2k}^2 \right) \right] - a_k^2 \omega_k^2 \left( 2 \left( d_k^2 + \gamma_k \right) - \sigma_{3k}^2 \right) - a_k^4 z_k^2 \left( 2d_k^2 - \sigma_{4k}^2 \right) + 2 \left( \sum_{j=1}^{2} \beta_{kj} E_j^* h_j - b_k \right) \left( d_k^2 + \sum_{j=1}^{2} \beta_{kj} S_k^* h_j \right) \right. \\
\left. \times u_k v_k + 2 \left( a_k^2 \epsilon_k v_k w_k + \gamma_k w_k z_k \right) + 2 \sum_{j=1}^{2} \beta_{kj} S_k^* (v_k - a_k u_k) \int_{r=0}^{\infty} f_j(r) v_j(t-r) dr + 2 \sum_{j=1}^{2} \beta_{kj} S_k^* (1 + a_k) h_j v_j^2 - \sum_{j=1}^{2} \beta_{kj} S_k^* (1 + a_k) \int_{r=0}^{\infty} f_j(r) v_j^2(t-r) dr \right\}.
\tag{4.12}
\]

In (4.12), we choose

\[
b_k = \frac{\sum_{j=1}^{2} \beta_{kj} S_k^* h_j}{\left( d_k^2 + \sum_{j=1}^{2} \beta_{kj} S_k^* h_j \right)}.
\tag{4.13}
\]

Then

\[
LV = \sum_{k=1}^{2} \left\{ -u_k^2 \left[ (a_k + b_k) \left( 2d_k^2 - \sigma_{ik}^2 \right) + 2 \sum_{j=1}^{2} a_k \beta_{kj} E_j^* h_j \right] - v_k^2 \left[ (1 + b_k) \left( 2 \sum_{j=1}^{2} \beta_{kj} S_k^* h_j - \sigma_{2k}^2 \right) \right] - a_k^2 \omega_k^2 \left( 2 \left( d_k^2 + \gamma_k \right) - \sigma_{3k}^2 \right) - a_k^4 z_k^2 \left( 2d_k^2 - \sigma_{4k}^2 \right) + 2 \left( \sum_{j=1}^{2} \beta_{kj} E_j^* h_j - b_k \right) \left( d_k^2 + \sum_{j=1}^{2} \beta_{kj} S_k^* h_j \right) \right. \\
\left. \times u_k v_k + 2 \left( a_k^2 \epsilon_k v_k w_k + \gamma_k w_k z_k \right) + 2 \sum_{j=1}^{2} \beta_{kj} S_k^* (v_k - a_k u_k) \int_{r=0}^{\infty} f_j(r) v_j(t-r) dr + 2 \sum_{j=1}^{2} \beta_{kj} u_k (v_k - a_k u_k) \int_{r=0}^{\infty} f_j(r) v_j(t-r) dr + 2 \sum_{j=1}^{2} \beta_{kj} S_k^* (1 + a_k) h_j v_j^2 - \sum_{j=1}^{2} \beta_{kj} S_k^* (1 + a_k) \int_{r=0}^{\infty} f_j(r) v_j^2(t-r) dr \right\}.
\tag{4.14}
\]

Moreover, using the Cauchy inequality to \(2a_k^2 \epsilon_k v_k w_k\) and \(2a_k^4 \gamma_k w_k z_k\), we can obtain

\[
2a_k^2 \epsilon_k v_k w_k \leq a_k^2 \epsilon_k \left( \frac{v_k^2}{a_k} + a_k w_k^2 \right),
\]
\[
2a_k^4 \gamma_k w_k z_k \leq a_k^4 \gamma_k \left( \frac{w_k^2}{a_k} + a_k z_k^2 \right).
\]
\[ 2 \sum_{j=1}^{2} \beta_{kj} S_k^j (v_k - a_k u_k) \int_{r=0}^{\infty} f_j(r)v_j(t-r)dr \leq a_k \sum_{j=1}^{2} \beta_{kj} S_k^j \left( u_k^2 + \int_{r=0}^{\infty} f_j(r)v_j^2(t-r)dr \right) + \sum_{j=1}^{2} \beta_{kj} S_k^j \left( v_k^2 + \int_{r=0}^{\infty} f_j(r)v_j^2(t-r)dr \right). \]

Substituting (4.15) into (4.14) as well as using \( 1 \geq \int_{r=0}^{\infty} f_k(r)dr = h_k > 0 \), yields

\[ LV \leq \sum_{k=1}^{2} \left\{ -u_k^2 \left[ b_k \left( 2d_k^2 - \sigma_{1k}^2 \right) - \sum_{j=1}^{2} a_k \beta_{kj} S_k^j \right] \right. \]
\[ -\nu_k^2 \left[ (1 + b_k) \sum_{j=1}^{2} \beta_{kj} S_k^j - \sigma_{2k}^2 \right] - a_k \left( e_k + \sum_{j=1}^{2} \beta_{kj} S_k^j \right) \]
\[ -a_k^2 u_k^2 \left( 2 \left( d_k^2 + \gamma_k \right) - \sigma_{2k}^2 - a_k (e_k + \gamma_k) \right) - a_k^4 z_k^2 \left( 2d_k^2 - \sigma_{4k}^2 - a_k \gamma_k \right) \]
\[ + 2 \sum_{j=1}^{2} \beta_{kj} u_k (v_k - a_k u_k) \int_{r=0}^{\infty} f_j(r)v_j(t-r)dr + \sum_{j=1}^{2} \beta_{kj} S_k^j \left( 1 + a_k \right) \nu_j^2 \right\} \]
\[ = L_0 V + 2 \sum_{k=1}^{2} \sum_{j=1}^{2} \beta_{kj} u_k (v_k - a_k u_k) \int_{r=0}^{\infty} f_j(r)v_j(t-r)dr, \]

where

\[ L_0 V \]
\[ = \sum_{k=1}^{2} \left\{ -u_k^2 \left[ b_k \left( 2d_k^2 - \sigma_{1k}^2 \right) - \sum_{j=1}^{2} a_k \beta_{kj} S_k^j \right] \right. \]
\[ -\nu_k^2 \left[ (1 + b_k) \sum_{j=1}^{2} \beta_{kj} S_k^j - \sigma_{2k}^2 \right] - a_k \left( e_k + \sum_{j=1}^{2} \beta_{kj} S_k^j \right) \]
\[ -a_k^2 u_k^2 \left( 2 \left( d_k^2 + \gamma_k \right) - \sigma_{2k}^2 - a_k (e_k + \gamma_k) \right) - a_k^4 z_k^2 \left( 2d_k^2 - \sigma_{4k}^2 - a_k \gamma_k \right) \]
\[ \left. \right\} \].

From (4.9) it follows that there exists \( a_k > 0 \) such that

\[ a_k < \min \left\{ \frac{b_k (2d_k^2 - \sigma_{1k}^2)}{\sum_{j=1}^{2} \beta_{kj} S_k^j}, \frac{2b_k \sum_{j=1}^{2} \beta_{kj} S_k^j - (1 + b_k) \sigma_{2k}^2}{e_k + \sum_{j=1}^{2} \beta_{kj} S_k^j}, \frac{2(d_k^2 + \gamma_k) - \sigma_{2k}^2}{e_k + \gamma_k}, \frac{2d_k^2 - \sigma_{4k}^2}{\gamma_k} \right\}. \]

Therefore, there exists \( C > 0 \) such that \( LV_0 \leq -C \|(u_k, v_k, w_k, z_k)\|^2 \).
Let us suppose that $P[|v_k(t)| < \delta_k] = 1$. Then

$$2 \sum_{j=1}^{2} \beta_{kj} u_k (v_k - a_k u_k) \int_{r=0}^{\infty} f_j(r) \sigma_j(t-r) \, dr \leq \sum_{j=1}^{2} \beta_{kj} \delta_k \left( u_k^2 (1 + 2a_k) + v_k^2 \right).$$

Therefore

$$LV \leq \sum_{k=1}^{2} \left\{ -u_k^2 \left[ b_k \left( 2d_k^c - \sigma_k^2 \right) - \sum_{j=1}^{2} a_k \beta_{kj} s_k^* - \sum_{j=1}^{2} \beta_{kj} \delta_k (1 + 2a_k) \right] \\
- \sigma_k^2 \left[ (1 + b_k) \left( \sum_{j=1}^{2} a_k \beta_{kj} s_k^* h_j - \sigma_k^2 \right) - a_k \left( e_k + \sum_{j=1}^{2} \beta_{kj} s_k^* \right) - \sum_{j=1}^{2} \beta_{kj} \delta_k \right] \\
- a_k^2 \sigma_k^2 \left( 2 \left( d_k^c + \gamma_k \right) - \sigma_k^2 - a_k (\epsilon_k + \gamma_k) \right) - a_k^2 \sigma_k^2 \left( 2 d_k^c - \sigma_k^2 - a_k \gamma_k \right) \right\}.$$

Hence for sufficiently small $\delta_k > 0$, $LV(x,t)$ is negative definite in a sufficiently small neighborhood of $x = 0$ for $t \geq 0$. According to Lemma 4.2, we therefore conclude that the zero solution of (4.2) is stochastically asymptotically stable in the large. The proof is complete.
