The nonfragile robust finite-time $L_2$-$L_\infty$ control problem for a class of nonlinear uncertain systems with uncertainties and time-delays is considered. The nonlinear parameters are considered to satisfy the Lipschitz conditions and the exogenous disturbances are unknown but energy bounded. By using the Lyapunov function approach, the sufficient condition for the existence of nonfragile robust finite-time $L_2$-$L_\infty$ controller is given in terms of linear matrix inequalities (LMIs). The finite-time controller is designed such that the resulting closed-loop system is finite-time bounded for all admissible uncertainties and satisfies the given $L_2$-$L_\infty$ control index. Simulation results illustrate the validity of the proposed approach.

1. Introduction

Time-delay is frequently a source of instability and always encounters in various engineering systems such as chemical processes, neural networks, and long transmission lines in pneumatic systems. Recently, many attentions have been paid to the solutions of deal with time-delay which existed in concerned systems, such as the input-output technique [1], delay partitioning method [2], and piecewise analysis method [3]. As an important class of nonlinear systems, the Lipschitzian nonlinear system also has drawn considerable attention in the past few decades. Among these researches, the studies of Lipschitz nonlinear systems with time-delays have received much attention [4–6].

However, it is necessary to point out that the results of the aforementioned papers about time-delayed Lipschitz systems are mostly based on Lyapunov stable theory. As we all known, Lyapunov stable theory pays more attention to the asymptotic pattern of systems over an infinite-time interval. But in some practical process, the main attention may be related to the behavior of the dynamical systems over fixed finite-time interval; for instance, large values of the states cannot be accepted in the presence of saturations. To deal with such situations, Dorato [7] first presented the concept of finite-time stability (or short-time stability) in 1961. In [8], Amato et al. first proposed the concept of finite-time boundedness; thereafter many attempts on finite-time control problems have been made [9–13]. However, to date, little work has been paid attention in finite-time controller design for Lipschitzian nonlinear system. The research topic is still open but challenging. And this is the key motivation of this paper.

On the other hand, in the feedback control schemes, there are often some perturbations appeared in controller gain, which may result from either the actuator degradations or the requirements of readjustment of controller gains during the controller implementation stage. Therefore, it is reasonable that any controller should be able to tolerate some level of controller gain variations, and this motivates many researchers to study the nonfragile controller problems [14–19]. Motivated by the benefits of nonfragile state feedback controller, we consider the nonfragile controller design problem in this paper.

In addition, energy to peak ($L_2$-$L_\infty$) control is of a great importance both in control theory and in engineering practice, because of its insensitivity to the exact knowledge of the statistics of the external disturbance signals. In [20], Rotea first introduced the $L_2$-$L_\infty$ performance index. After that many researchers have paid attention in $L_2$-$L_\infty$ control
problems. For example, in [21], the authors studied the $L_2$-$L_\infty$ controller design problem for continuous-time multiple delayed linear systems; in [22], the problem of $L_2$-$L_\infty$ control for a class of uncertain singular systems with time-delay and norm-bounded parameter uncertainties was investigated by the researchers. For more details of the literatures related to $L_2$-$L_\infty$ control schemes, the readers can refer to [21–24] and the references therein.

In short, to the best knowledge of authors, the problem of nonfragile robust finite-time $L_2$-$L_\infty$ control for a class of uncertain Lipschitz nonlinear systems with time-delays is not studied at present. This motivates our research.

This paper deals with the problem of nonfragile robust finite-time $L_2$-$L_\infty$ control for a class of Lipschitz nonlinear systems with time-delays and uncertainties, and the nonlinear function is assumed to satisfy the Lipschitz conditions. The uncertain parameters are assumed to be time varying and energy bounded. The purpose is to construct a nonfragile state feedback controller such that the resulting closed-loop system is finite-time bounded and satisfies the given $L_2$-$L_\infty$ index. By using the Lyapunov function approach and linear matrix inequality techniques, a sufficient condition for the existence of a nonfragile state feedback controller is given and an explicit expression of this controller is presented. Meanwhile, this problem is reduced to an optimization problem under the constraint of LMs. Finally, a simulation example illustrates the effectiveness of the developed techniques.

The paper is organized as follows. In Section 2, the system description along with necessary assumption is given. Section 3 provides the main results. A simulation example is provided to illustrate the results of the paper in Section 4. Conclusion follows in Section 5.

Notation. In the sequel, if not explicitly stated, matrices are assumed to have compatible dimensions. I and 0 represent the identity matrix and a zero matrix. The notation $M > (\geq, <, \leq) 0$ is used to denote a symmetric positive-definite (positive semidefinite, negative-definite, negative semidefinite) matrix. $\lambda_{\min}(\cdot), \lambda_{\max}(\cdot)$ denote the minimum and the maximum eigenvalue of the corresponding matrix, respectively. $L_2[0 + \infty)$ denotes the Euclidean norm for vectors or the spectral norm of matrices. $L_2^n[0 N]$ is the space of $n$-dimensional square integrable function vector over $[0 N]$. In symmetric black matrices, we use * that represents the elements below the main diagonal of a symmetric block matrix. The superscript T represents the transpose.

2. Preliminaries and Problem Statement

Consider a class of Lipschitz nonlinear systems with time-delay and parameter uncertainties described by the following equations:

$$
\dot{x}(t) = [A + \Delta A(t)]x(t) + [A_d + \Delta A_d(t)]x(t-d) + Bu(t) + [G + \Delta G(t)]w(t) \\
+ [F + \Delta F(t)]f(x(t), x(t-d)),
$$

$$
y(t) = [C + \Delta C(t)]x(t) + Du(t),
$$

where $x(t) \in \mathbb{R}^n$ is the state, $x(t-d) \in \mathbb{R}^n$ is the constant time-delay state, $u(t) \in \mathbb{R}^p$ is the controlled input, $w(t) \in \mathbb{R}^q$ is the disturbance input that belongs to $L_2[0 + \infty)$, $f(x(t), x(t-d)) \in \mathbb{R}^n \times \mathbb{R}^n = \mathbb{R}^{nv}$ is the nonlinear function which represents the known nonlinear disturbance related to the state and the time-delay state, and $\varphi(t) \in L_2[-d 0]$ is a continuous vector-valued initial function. In addition, $A, A_d, B, G, F, C$, and $D$ are known real matrices, and $\Delta A(t), \Delta A_d(t), \Delta G(t), \Delta F(t)$, and $\Delta C(t)$ are unknown time-variant matrices representing the norm-bounded parameter uncertainties and satisfy the following form:

$$
\begin{bmatrix}
\Delta A(t) \\
\Delta A_d(t) \\
\Delta G(t) \\
\Delta F(t) \\
\Delta C(t)
\end{bmatrix} \\
= 
\begin{bmatrix}
M_1 \\
M_2 \\
I \\
S_1 \\
S_2 \\
S_3 \\
S_4
\end{bmatrix} \Gamma(t) \leq I,
$$

where $M_1, M_2, S_1, S_2, S_3$, and $S_4$ are known real constants matrices and $\Gamma(t)$ is the time-varying unknown matrix function with Lebesgue norm measurable elements.

Remark 1. The parameter uncertainty structure as in (2) and (3) has been widely used in the existing literatures, such as [22, 24, 25]. In many practical applications, the systems parameter uncertainties can be either exactly modeled or overbounded by (3). Note that the unknown matrix function $\Gamma(t)$ is time-varying, therefore it can be allowed to be state-dependent in some case, that is, $\Gamma(t) = \Gamma(t, x(t))$.

The following preliminary assumptions are made for system (1).

Assumption 1. For any given positive number $\delta$ and constant time $T$, the external disturbances input $w(t)$ is time-varying and satisfies

$$
\int_0^T w^T(t)w(t)\,dt \leq \delta, \quad \delta \geq 0.
$$

Assumption 2. $f(x(t), x(t-d)) : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^{nv}$ is a known nonlinear function which satisfies the following Lipschitz conditions:

(i) $f(0,0) = 0$;

(ii) $\|f(x(t), x(t-d))\| \leq \|\eta_1 x(t)\| + \|\eta_2 x(t-d)\|,$

where the weighting matrices $\eta_1$ and $\eta_2$ are known real constant matrices.

Remark 2. The above Lipschitz condition can be considered as an extension of the Lipschitz condition mentioned in [19]. When $\eta_1 = \text{diag} \sqrt{\alpha} \sqrt{\alpha} \ldots \sqrt{\alpha}$ and $\eta_2 = \text{diag} \sqrt{\beta} \sqrt{\beta} \ldots \sqrt{\beta}$, the Lipschitz condition in Assumption 2 will reduce to (4) [19].
Our aim is to develop a nonfragile state feedback controller:

\[ u(t) = [K + \Delta K(t)] x(t), \]

where the matrix \( K \) is the controller gain to be determined and \( \Delta K(t) \) is the controller gain variations. Here, we consider the additive controller gain variation, that is,

\[ \Delta K(t) = H \rho(t) N, \quad \rho^T(t) \rho(t) \leq I, \]

where \( H \) and \( N \) are known matrices, and \( \rho(t) \) is unknown but norm bounded.

Remark 3. The controller gain perturbations can result from the actuator degradations, as well as from the requirements for readjustment of controller gain during the controller implementation stage. Thus, perturbations in the controller gains are modeled here as uncertain gains that are dependent on the uncertain parameters [6]. The models of additive uncertainties and multiplicative uncertainties are used to describe the controller gain variations. For more results on this topic, we refer readers to [6, 17, 18] and the references therein.

By the nonfragile state feedback controller (5), the closed-loop system can be obtained as follows:

\[ \dot{x}(t) = \tilde{A}x(t) + \tilde{A}_d x(t - d) + \tilde{G}w(t) + \tilde{F}f(x(t), x(t - d)), \]

\[ y(t) = \tilde{C}x(t), \]

where \( \tilde{A} = A + \Delta A(t), \tilde{A}_d = A_d + \Delta A_d(t), \tilde{G} = G + \Delta G(t), \tilde{F} = F + \Delta F(t), \tilde{C} = C + \Delta C(t), \tilde{A} = A + BK, \tilde{C} = C + DK, \Delta A(t) = \Delta A(t) + B \Delta K(t), \Delta C(t) = \Delta C(t) + D \Delta K(t). \]

To formulate the problem addressed in this paper, we give the following definitions first.

Definition 4 (FTB). For given constants \( \varsigma_1 > 0, \varsigma_2 > 0, \) and \( T > 0 \) and a symmetric matrix \( R > 0 \), the closed-loop system (7) is said to be robust finite-time bounded (FTB) with respect to \( (\varsigma_1 \varsigma_2 \delta T R) \), if there exists a constant \( \varsigma_2 > \varsigma_1 \), such that the following relation holds for all the external disturbance \( w(t) \):

\[ x^T(t_0) Rx(t_0) \leq \varsigma_1 \Rightarrow x^T(t) Rx(t) < \varsigma_2, \]

\[ \forall t_0 \in [-d, 0], \quad t \in [0, T]. \]

Remark 5. In fact, if the closed-loop system (7) does not exist the exogenous disturbance input, that is, \( w(t) = 0 \), the concept of FTB reduces to finite-time stable (FTS) [8, 11]. That is to say, a system is FTB, if given a bound initial condition and characterization of the set of admissible inputs, then the system states remain below the prescribed limit for all inputs in the bounded set.

Definition 6. The state-feedback controller (5) is said to be a nonfragile robust finite-time \( L_2 - L_\infty \) controller with disturbance attenuation \( \gamma > 0 \) for system (1) if the closed-loop system (7) is FTB in the sense of Definition 4, and there exists a positive real constant \( \gamma > 0 \) such that

\[ \|y(t)\|_{\infty}^2 \leq \gamma^2 \|w(t)\|_{\infty}^2, \]

where \( \|y(t)\|_{\infty} \) is the controller gain variations. Here, we consider the additive controller gain variation, that is,

\[ \Delta K(t) = H \rho(t) N, \quad \rho^T(t) \rho(t) \leq I, \]

where \( H \) and \( N \) are known matrices, and \( \rho(t) \) is unknown but norm bounded.

Remark 3. The controller gain perturbations can result from the actuator degradations, as well as from the requirements for readjustment of controller gain during the controller implementation stage. Thus, perturbations in the controller gains are modeled here as uncertain gains that are dependent on the uncertain parameters [6]. The models of additive uncertainties and multiplicative uncertainties are used to describe the controller gain variations. For more results on this topic, we refer readers to [6, 17, 18] and the references therein.

By the nonfragile state feedback controller (5), the closed-loop system can be obtained as follows:

\[ \dot{x}(t) = \tilde{A}x(t) + \tilde{A}_d x(t - d) + \tilde{G}w(t) + \tilde{F}f(x(t), x(t - d)), \]

\[ y(t) = \tilde{C}x(t), \]

where \( \tilde{A} = A + \Delta A(t), \tilde{A}_d = A_d + \Delta A_d(t), \tilde{G} = G + \Delta G(t), \tilde{F} = F + \Delta F(t), \tilde{C} = C + \Delta C(t), \tilde{A} = A + BK, \tilde{C} = C + DK, \Delta A(t) = \Delta A(t) + B \Delta K(t), \Delta C(t) = \Delta C(t) + D \Delta K(t). \]

To formulate the problem addressed in this paper, we give the following definitions first.

Definition 4 (FTB). For given constants \( \varsigma_1 > 0, \delta > 0, \) and \( T > 0 \) and a symmetric matrix \( R > 0 \), the closed-loop system (7) is said to be robust finite-time bounded (FTB) with respect to \( (\varsigma_1 \varsigma_2 \delta T R) \), if there exists a constant \( \varsigma_2 > \varsigma_1 \), such that the following relation holds for all the external disturbance \( w(t) \):

\[ x^T(t_0) Rx(t_0) \leq \varsigma_1 \Rightarrow x^T(t) Rx(t) < \varsigma_2, \]

\[ \forall t_0 \in [-d, 0], \quad t \in [0, T]. \]

Remark 5. In fact, if the closed-loop system (7) does not exist the exogenous disturbance input, that is, \( w(t) = 0 \), the concept of FTB reduces to finite-time stable (FTS) [8, 11]. That is to say, a system is FTB, if given a bound initial condition and characterization of the set of admissible inputs, then the system states remain below the prescribed limit for all inputs in the bounded set.

3. Main Results

In this section, we will solve the problem of nonfragile robust finite-time \( L_2 - L_\infty \) controller design for a class of Lipschitz uncertain nonlinear time-delay systems formulated in the previous section based on LMI approach. The following results actually present the FTB condition for closed-loop system (7) with time-delays.

Theorem 9. For given \( \varsigma_1 > 0, \delta > 0, T > 0, \epsilon > 0, \alpha > 0 \) and weighting matrices \( \eta_1, \eta_2, R > 0 \), the closed-loop controlled system (7) is FTB with respect to \( (\varsigma_1 \varsigma_2 \delta T R) \), if there exists constant \( \varsigma_2 > 0 \), symmetric positive-definite matrices \( P \) and \( Q > 2\epsilon^2 \eta_2^T \eta_2 \), such that

\[ \Omega_1 = \begin{bmatrix} \Pi_{11} & \Pi_{12} & \Pi \end{bmatrix} < 0, \]

\[ c_1 (\lambda_1 + d \lambda_2) + \delta \left( 1 - e^{-\alpha T} \right) < \lambda_2 \varsigma_2 e^{-\alpha T}, \]

where \( \Pi_{11} = \tilde{A}^T P + \tilde{A}^T \tilde{P} A + Q - \alpha P + 2 \epsilon \eta_1^T \eta_1 + \epsilon^2 \frac{P \tilde{F}^T \tilde{F} + \tilde{F}^T \tilde{F}}{2}, \)

\[ \Pi_{12} = -Q + 2 \epsilon \eta_1^T \eta_1, \quad \tilde{P} = \tilde{R}^{-1/2} \tilde{P} \tilde{R}^{1/2}, \quad \tilde{Q} = \tilde{R}^{-1/2} \tilde{Q} \tilde{R}^{1/2}, \quad \lambda_1 = \lambda_{\min}(\tilde{P}), \quad \lambda_2 = \lambda_{\min}(\tilde{Q}). \]

Proof. Choose a Lyapunov function candidate \( V(x(t)) \) as

\[ V(x(t)) = x^T(t) Px(t) + \int_{t-d}^t x^T(r) Qx(r) dr. \]
Along the trajectories of system (7), the corresponding time derivation of \( V(x(t)) \) is given by

\[
\dot{V}(x(t)) = x^T(t) P x(t) + \dot{x}^T(t) P \dot{x}(t) + \left[ x^T(t) Q x(t) \right]_{t-d}^t \\
= x^T(t) \left( \bar{A}^T P + P \bar{A} + Q \right) x(t) \\
+ x^T(t) P \bar{A}_d x(t-d) + x^T(t-d) \bar{A}_d^T P x(t) \\
+ x^T(t) P \bar{G} w(t) + w^T(t) \bar{G}^T P x(t) \\
- x^T(t-d) Q x(t-d) - 2f^T(x(t), x(t-d)) \bar{F}^T P x(t). 
\]

(15)

Using Assumption 2, we have

\[
\|f(x(t), x(t-d))\|^2 \leq 2\|\eta_1 x(t)\|^2 + 2\|\eta_2 x(t-d)\|^2. 
\]

(16)

Considering Lemma 7, we can obtain the following relation for any scalar \( \varepsilon > 0 \)

\[
2f^T(x(t), x(t-d)) \bar{F}^T P x(t) \\
\leq \varepsilon f^T(x(t), x(t-d)) f(x(t), x(t-d)) \\
+ \varepsilon^{-1} x^T(t) \bar{P} \bar{F}^T P x(t) \\
\leq x^T(t) \left( 2\eta_1^T \eta_1 + \varepsilon^{-1} \bar{P} \bar{F}^T \bar{P} \right) x(t) \\
+ x^T(t-d) \left( 2\eta_2^T \eta_2 \right) x(t-d). 
\]

(17)

Hence, relation (15) can be rewritten as

\[
\dot{V}(x(t)) \\
\leq x^T(t) \left( \bar{A}^T P + P \bar{A} + Q + 2 \eta_1^T \eta_1 + \varepsilon^{-1} \bar{P} \bar{F}^T \bar{P} \right) x(t) \\
+ x^T(t) P \bar{A}_d x(t-d) + x^T(t-d) \bar{A}_d^T P x(t) \\
+ x^T(t) P \bar{G} w(t) + w^T(t) \bar{G}^T P x(t) \\
+ x^T(t-d) \left( -Q + 2 \eta_2^T \eta_2 \right) x(t-d). 
\]

(18)

Define the following function:

\[
J_1 = \dot{V}(x(t)) - \alpha V(x(t)) - \alpha \omega^T(t) w(t). 
\]

(19)

Considering (18) and (14), we obtain

\[
J_1 + \alpha \int_{t-d}^t x^T(\tau) Q x(\tau) d\tau = \zeta^T \Omega_1 \zeta < 0, 
\]

(20)

where \( \zeta = [x^T(t) \ x^T(t-d) \ \omega^T(t)]^T \).

According to \( \alpha > 0 \) and \( Q > 0 \), inequality (20) implies \( J_1 < 0 \). Thus, by using (19), we get

\[
\dot{V}(x(t)) < \alpha V(x(t)) + \alpha \omega^T(t) w(t). 
\]

(21)

Pre- and postmultiplying (20) by \( e^{-\alpha t} \), it yields

\[
\frac{d}{dt} \left( e^{-\alpha t} V(x(t)) \right) < \alpha e^{-\alpha t} \omega^T(t) w(t). 
\]

(22)

Integrating the aforementioned inequality between 0 and \( t \), it follows that

\[
e^{-\alpha t} V(x(t)) - V(x(0)) < \alpha \int_0^t e^{-\alpha \tau} \omega^T(s) w(s) d\tau.
\]

(23)

Then, the above inequality is equivalent to

\[
V(x(t)) < e^{\alpha t} V(x(0)) + \alpha e^{\alpha t} \int_0^t e^{-\alpha \tau} \omega^T(s) w(s) d\tau. 
\]

(24)

Noting that \( \bar{P} = R^{-1/2} P R^{-1/2}, \bar{Q} = R^{-1/2} Q R^{-1/2} \), it follows from (14) that

\[
e^{\alpha t} V(x(0)) + \alpha e^{\alpha t} \int_0^t e^{-\alpha \tau} \omega^T(s) w(s) d\tau \\
= e^{\alpha t} x^T(0) P x(0) + e^{\alpha t} \int_0^t x^T(\tau) Q x(\tau) d\tau \\
+ \alpha e^{\alpha t} \int_0^t e^{-\alpha \tau} \omega^T(s) w(s) d\tau \\
\leq e^{\alpha t} \lambda_{\max} \left( \bar{P} \right) c_1 + e^{\alpha t} \lambda_{\max} \left( \bar{Q} \right) c_1 + \delta e^{\alpha t} \left( 1 - e^{-\alpha T} \right) \\
= e^{\alpha t} \left[ c_1 \lambda_1 + \delta \right] - \lambda_{\min} \left( \bar{P} \right) x^T(t) R x(t). 
\]

(25)

On the other hand, the following condition holds:

\[
V(x(t)) = x^T(t) P x(t) + \int_{t-d}^t x^T(\tau) Q x(\tau) d\tau \\
\geq x^T(t) P x(t) \geq \lambda_{\min} \left( \bar{P} \right) x^T(t) R x(t) \\
= \lambda_2 x^T(t) R x(t). 
\]

(26)

Combining (24), (25), and (26), we can get

\[
x^T(t) R x(t) \leq \frac{c_1 \left( \lambda_1 + \delta \right) + \delta \left( 1 - e^{-\alpha T} \right)}{\lambda_2 e^{\alpha T}}. 
\]

(27)

Recalling condition (13), it implies that for \( \forall t \in [0 \ T] \), \( x^{T}(t) R x(t) < c_2 \). This completes the proof. \( \square \)

**Remark 10.** Without the time-delay in the resulted closed-loop system (7), the system will reduce to the system which has been investigated in [25, 28]. In this case, one can get the sufficient conditions of FTB for the aforementioned system from Theorem 9 via a simple transformation. Furthermore, if there is also no nonlinear function in the aforementioned system, then Theorem 9 reduces to a form which has been given in [8, Lemma 6] or [13, Lemma 1].

Theorem 9 gives the sufficient condition of FTB for the resulting closed-loop controlled system (7). Then, we will apply the results in Theorem 11 to solve the problem of nonfragile robust finite-time \( L_2-L_{\infty} \) controller design.
Theorem 11. For given \( c_1 > 0 \), \( \delta > 0 \), \( T > 0 \), \( \varepsilon > 0 \), \( \alpha > 0 \), and weighting matrices \( \eta_1, \eta_2, R > 0 \), the closed-loop system (7) is FTB with respect to \( (c_1, c_2, \delta, T, R) \) and satisfies the cost function (9) for all admissible \( w(t) \) with the constraint condition and all admissible uncertainties, if there exist constants \( c_2 > 0 \), \( \beta > 0 \), symmetric positive-definite matrices \( P \) and \( Q > 2\eta_1^T \eta_2 \), such that conditions (12), (13), and (28), and the following inequality hold:

\[
\Omega_2 = \begin{bmatrix} -P & \overline{C}^T \\ * & -\beta I \end{bmatrix} < 0. \tag{28}
\]

Proof. Defining the same Lyapunov function as Theorem 9. Under the zero initial state condition \( \phi(t) = 0, t \in [0,0] \), we can rewrite (24) as

\[
V(x(t)) < \alpha e^{at} \int_0^t e^{-as} w^T(s) w(s) ds. \tag{29}
\]

Hence, from (14) and \( \forall t \in [0,T] \), we can get

\[
x^T(t) P x(t) < V(x(t)) < \alpha e^{at} \int_0^t e^{-as} w^T(s) w(s) ds \tag{30}
\]

\[
< \alpha e^{at} \int_0^T w^T(t) w(t) dt.
\]

Furthermore, from (28) and using Schur complement, we have

\[
\overline{C}^T \overline{C} < \beta P. \tag{31}
\]

Then, it follows

\[
y^T(t) y(t) = x^T(t) \overline{C}^T \overline{C} x(t) < \beta x^T(t) P x(t) < \beta \alpha e^{at} \int_0^T w^T(t) w(t) dt.
\]

Taking the maximum value of \( \|y(t)\|_\infty \), we have \( \|y(t)\|_\infty < \beta \alpha e^{at} \|w(t)\|_2 \) with \( t \in [0,T] \). Therefore, condition (9) can be guaranteed by letting \( \gamma = \sqrt{\beta \alpha e^{at}} \). This completes the proof. \( \square \)

In order to solve Theorem II, we can obtain the relevant algorithm by imposing further LMI constraints in the design phase. Substituting the corresponding matrices into matrix inequalities (12), (13), and (28), we can draw the following Theorem 12.

Theorem 12. For given \( c_1 > 0 \), \( \delta > 0 \), \( T > 0 \), \( \varepsilon > 0 \), \( \alpha > 0 \), and weighting matrices \( \eta_1, \eta_2, R > 0 \), the closed-loop system (7) is FTB with respect to \( (c_1, c_2, \delta, T, R) \), exists a nonfragile state-feedback controller gain \( K = YX^{-1} \), and satisfies the cost function (9) for all admissible \( w(t) \) with the constraint condition and all admissible uncertainties, if there exist positive constants \( c_2, \beta, \mu_1, \mu_2, \mu_3, \) and \( \mu_4 \), symmetric positive-definite matrices \( X, Q, \) and \( Z, \) and real matrix \( Y, \) such that the following LMIs hold:

\[
\begin{bmatrix}
\Sigma_{11} & A_d & G & \eta_1^T & F & X S_1^T & X N^T \\
* & -Q & 0 & \eta_2^T & 0 & S_2^T & 0 \\
* & -\alpha I & 0 & 0 & 0 & 0 & 0 \\
* & * & -\frac{1}{2} e^{-1} I & 0 & 0 & 0 & 0 \\
* & * & * & -\varepsilon I & S_4^T & 0 & 0 \\
* & * & * & * & -\mu_1 I & 0 & 0 \\
* & * & * & * & * & -\mu_2 I & 0 \\
\end{bmatrix} < 0, \tag{33}
\]

\[
\begin{bmatrix}
-X & \Sigma_{12} & X S_3^T & X N^T \\
* & \Sigma_{22} & 0 & 0 \\
* & * & -\mu_3 I & 0 \\
* & * & * & -\mu_4 I \\
\end{bmatrix} < 0, \tag{34}
\]

\[
\sigma_1 R^{-1} < X < R^{-1}, \tag{35}
\]

\[
0 < Q < \sigma_3 R, \tag{36}
\]

\[
\begin{bmatrix}
c_1 d \sigma_2 + \delta (1 - e^{-at}) - c_2 e^{-at} \sqrt{\sigma_2} & 0 \\
\sqrt{\sigma_2} & -\sigma_1 \end{bmatrix} < 0, \tag{37}
\]

where \( \Sigma_{11} = X A^T + AX + Z - \alpha X + \mu_1 M_1 + \mu_2 BH + \mu_3 B^T Y + \mu_4 D^T, \Sigma_{12} = XC^T + Y^T D^T, \Sigma_{22} = -\beta I + \mu_3 M_2 + \mu_4 D^T D^T. \)

Proof. In order to deal with the uncertainties in inequality (12), we can rewrite it as the following inequality:

\[
\overline{\Omega}_i = \begin{bmatrix}
\overline{\Pi}_{11} & P \overline{A}_d & \overline{P} G & \eta_1^T & \overline{P} F \\
* & -Q & 0 & \eta_2^T & 0 \\
* & -\alpha I & 0 & 0 & 0 \\
* & * & -\frac{1}{2} e^{-1} I & 0 & 0 \\
* & * & * & -\varepsilon I & 0 \\
\end{bmatrix} < 0, \tag{38}
\]

where \( \overline{\Pi}_{11} = \overline{A}^T P + P \overline{A} + Q - \alpha I. \)

Thus, the aforementioned inequality (38) is equivalent to

\[
\overline{\Omega}_i = \overline{\Omega}_i + \overline{\Omega}_i \Delta < 0, \tag{39}
\]

where

\[
\overline{\Pi}_{11} = \overline{A}^T P + P \overline{A} + Q - \alpha I.
\]
\[ \tilde{\Omega}_{1\Delta} = \begin{bmatrix} \Delta \tilde{P}_{11} & P \Delta A_d(t) & \Delta \Gamma(t) & 0 & 0 \\ * & 0 & 0 & 0 & 0 \\ * & * & 0 & 0 & 0 \\ * & * & * & 0 & 0 \\ * & * & * & * & 0 \end{bmatrix}, \]

Moreover, noticing the uncertainties which were described as the form in (2) and (6), we have
\[ \tilde{\Omega}_{1\Delta} = \begin{bmatrix} J_1 \Gamma(t) L_1 + [J_1 \Gamma(t) L_1]^T + J_2 \rho(t) L_2 + [J_2 \rho(t) L_2]^T \end{bmatrix}, \]

where
\[ J_1 = \begin{bmatrix} PM_1 \\ 0 \\ J_2 = \begin{bmatrix} PBH \\ 0 \\ 0 \end{bmatrix}, \]

\[ L_1 = \begin{bmatrix} S_1 & S_2 & S_3 \end{bmatrix}, \]

On the other hand, considering the uncertainties in inequality (34), we have
\[ \Omega_2 = \tilde{\Omega}_2 + \tilde{\Omega}_{2\Delta} < 0, \]

where \[ \tilde{\Omega}_2 = \begin{bmatrix} -P \Gamma^T \\ \tilde{\Omega}_{2\Delta} = \begin{bmatrix} 0 \Delta \Gamma(t) \end{bmatrix}. \]

Using Lemma 8, we know the following inequality holds by real positive scalars \( \mu_3 \) and \( \mu_4 \):
\[ \Omega_{2\Delta} = \begin{bmatrix} J_3 \Gamma(t) L_3 + [J_3 \Gamma(t) L_3]^T + J_4 \rho(t) L_4 + (J_4 \rho(t) L_4)^T \end{bmatrix}, \]

\[ \leq \mu_3 J_3 \Gamma^T L_3 + \mu_3 L_3 L_3 + \mu_4 J_4 L_4 + \mu_4 L_4 L_4. \]

Thus, inequality (39) can be guaranteed by
\[ \tilde{\Omega}_1 + \mu_1 J_1 \Gamma^T + \mu_1 L_1 L_1 + \mu_2 J_2 \Gamma^T + \mu_2 L_2 L_2 < 0. \]

Rewriting inequality (44) and applying Schur complement, we have
\[
\tilde{\Omega}_1 = \begin{bmatrix} \Delta \tilde{P}_{11} & P \Delta A_d(t) & \Delta \Gamma(t) & 0 & 0 \\ * & 0 & 0 & 0 & 0 \\ * & * & 0 & 0 & 0 \\ * & * & * & 0 & 0 \\ * & * & * & * & 0 \end{bmatrix} < 0, \]

where \( \Delta \tilde{P}_{11} = \Delta \tilde{P} + \tilde{P} \Delta A \tilde{P} - \Delta \Gamma(t) \tilde{P} + \tilde{P} \Delta \Gamma(t) \tilde{P} - \alpha I + \mu_1 PM_1 M_1^T \tilde{P} + \mu_2 PBHH^T \tilde{B}^T \tilde{P}. \)
4. Simulation Example

Consider system (1) with the following parameters:

\[
A = \begin{bmatrix} -1.0 & 2.0 \\ 0.5 & -1.2 \end{bmatrix}, \quad A_d = \begin{bmatrix} -1.0 & 0.5 \\ 1.2 & 0.4 \end{bmatrix},
\]
\[
B = \begin{bmatrix} 1.0 \\ 0.8 \end{bmatrix}, \quad G = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix}, \quad F = \begin{bmatrix} 0.6 & -0.3 \\ 1.0 & 0.4 \end{bmatrix},
\]
\[
C = \begin{bmatrix} 1.5 & 1.7 \end{bmatrix}, \quad D = \begin{bmatrix} 1.5 \end{bmatrix}, \quad M_1 = \begin{bmatrix} 1.0 \\ -0.8 \end{bmatrix},
\]
\[
M_2 = \begin{bmatrix} 0.6 \end{bmatrix}, \quad S_1 = \begin{bmatrix} 1.2 & 0.6 \end{bmatrix}, \quad S_2 = \begin{bmatrix} 0.7 & 1.0 \end{bmatrix},
\]
\[
S_3 = \begin{bmatrix} 0.9 \end{bmatrix}, \quad S_4 = \begin{bmatrix} 0.4 & 1.1 \end{bmatrix}.
\]

In addition, we set \(c_1 = 0.5\), \(\delta = 1\), \(T = 4\), \(\epsilon = 1.2\), \(\alpha = 0.5\), \(d = 0.2\), and \(R = \begin{bmatrix} 1.2 & 0.4 \\ 0.4 & 0.8 \end{bmatrix}\). The nonlinear function part in system (1) is chosen as the following form:

\[
f(x(t), x(t-d)) = \begin{bmatrix} 0.3 \sin x_1(t) + 0.5 \sin x_1(t-d) \\ 0.4 \sin x_2(t-d) \end{bmatrix}.
\]

Then, for any \(x(t) = [x_1, x_2]^T\) and \(x(t-d) = [x_{1d}, x_{2d}]^T \in \mathbb{R}^2\), we have

\[
\|f(x(t), x(t-d))\|^2 = 0.09 \sin^2 x_1 + 0.25 \sin^2 x_{1d} + 0.3 \sin x_1 \sin x_{1d} + 0.16 \sin^2 x_{2d} \\
\leq 2 \left(0.12 x_1^2 + 0.2 x_{1d}^2 + 0.08 x_{2d}^2\right).
\]

According to (16), we select the weighting matrices as follows

\[
\eta_1 = \begin{bmatrix} \sqrt{0.12} & 0 \\ 0 & 0 \end{bmatrix}, \quad \eta_2 = \begin{bmatrix} \sqrt{0.2} & 0 \\ 0 & \sqrt{0.08} \end{bmatrix}.
\]

Remark 16. It is necessary to point out that the selection of the above weighting matrices not only needs to satisfy Assumption 2 but also needs to ensure that the LMI (33) is feasible. Namely, the LMI designed in this note actually puts a constraint on the size of the above weighting matrices.

By resorting to MATLAB LMIs Toolbox, solving Theorem 12 and Remark 13, respectively, we can obtain the following solutions under the above two cases.

**Case 1.** Let \(H = [0.3], N = [0.3 \ 0.2], \rho(t) = (0.5/(1 + t^2))I, \Gamma(t) = 0.8 \sin(t)I\). Solving Theorem 12, which considering the additive controller gain variation, we get

\[
X = \begin{bmatrix} 0.6336 & -0.3118 \\ -0.3118 & 0.9425 \end{bmatrix}, \quad Y = \begin{bmatrix} -0.2802 & -0.7564 \\ 0.6336 & 0.9425 \end{bmatrix},
\]
\[
K = YX^{-1} = \begin{bmatrix} -1.0000 & -1.1333 \end{bmatrix},
\]

with scalars value \(\beta = 45.4950\), \(\gamma = 12.9647\), and \(c_2 = 86.0363\).
Case 2. Let $H = [0.3]$, $N = [0.5]$, $\rho(t) = (0.5/(1 + t^2))I$, and $\Gamma(t) = 0.8 \sin(t)I$. Solving Remark 13, which is considering the multiplicative controller gain variation, we get

$$X = \begin{bmatrix} 0.6356 & -0.3100 \\ -0.3100 & 0.9439 \end{bmatrix}, \quad Y = \begin{bmatrix} -0.2644 & -0.6864 \end{bmatrix},$$

$$K = YX^{-1} = \begin{bmatrix} -0.9176 & -1.0285 \end{bmatrix},$$

(59)

with scalars value $\beta = 45.5722$, $\gamma = 12.9757$, and $c_2 = 86.1562$.

In this note, with the initial states $x_0 = [0.5 \ 0.2]^T$ and the disturbance input is chosen as

$$w(t) = \frac{0.6 \sin(20t)}{1 + t^2}, \quad t \geq 0,$$

(60)

The trajectories of uncontrolled system state $x(t)$ are depicted as Figure 1. The states and output simulation curves of closed-loop controlled system are, respectively, shown in Figures 2, 3, and 4 with the simulation time $t \in [0 \ 25]$.

Figure 5 shows the evolution of $x^T(t)Rx(t)$ ($t \in [0 \ 4]$) of the controlled system (7).

By calculation, we have $\|y(t)\|_\infty/\|w(t)\|_2 = 0.5995$ (Case 1) and $\|y(t)\|_\infty/\|w(t)\|_2 = 0.7053$ (Case 2). According to the above computing results and the simulation results, one can know that the nonfragile state feedback controller which was designed in this note can effectively guarantee that the concerned system (1) not only is finite-time bounded in fixed finite-time interval $t \in [0 \ 4]$ but also with an $L_2-L_\infty$ disturbance performance level.

Remark 17. It should be pointed out that in the simulation example, according to Definition 4, as long as the choice of $c_1$ with the initial states is satisfied to $\|x_0^T Rx_0\| \leq c_1$. Then, the nonfragile state feedback controlled system is FTB (i.e., the closed-loop system trajectories stay within a given bound) and satisfies the $L_2-L_\infty$ constraint condition (9).

5. Conclusions

In this paper, we have studied the nonfragile robust finite-time $L_2-L_\infty$ control problem for a class of uncertain Lipschitz nonlinear systems with time-delays. By using the Lyapunov function approach and linear matrix inequality techniques, a sufficient condition for the existence of nonfragile robust finite-time $L_2-L_\infty$ controller has been derived. Based on this condition, an optimization algorithm is provided to find nonfragile optimal control. Finally, a simulation example is presented to illustrate the effectiveness and applicability of the proposed approach.
