We presented some maximal and minimal fixed point theorems of set-valued monotone mappings with respect to a partial order introduced by a vector functional in cone metric spaces. In addition, we proved not only the existence of maximal and minimal fixed points but also the existence of the largest and the least fixed points of single-valued increasing mappings. It is worth mentioning that the results on single-valued mappings in this paper are still new even in the case of metric spaces and hence they indeed improve the recent results.

1. Introductions

Throughout this paper, let \((X, d)\) be a complete cone metric space over a total minihedral and continuous cone \(P\) of a normed vector space \(E\). A vector functional \(\varphi : X \rightarrow E\) introduces a partial order \(<\) on \(X\) as follows:

\[
x < y \iff d(x, y) \leq \varphi(x) - \varphi(y),
\]

for all \(x, y \in X\), where \(\leq\) is the partial order on \(E\) determined by the cone \(P\). Using the partial order introduced by the vector functional \(\varphi\), Agarwal and Khamsi [1] extended Caristi’s fixed point theorem [2] to the case of cone metric spaces and proved that all mapping \(T : X \rightarrow X\) (resp., \(T : X \rightarrow 2^X\)) such that

\[
\forall x \in X, \quad x < Tx \quad (\text{resp., } \forall x \in X, \exists y \in Tx, \ x < y)
\]

has a fixed point provided that \(\varphi\) is lower semicontinuous and bounded below on \(X\). In [1, 3], the authors studied Kirk’s problem [4, 5] in the case of cone metric spaces and obtained some generalized Caristi’s fixed point theorems in cone metric spaces. For the researches on the generalization of primitive Caristi’s result in the case of metric spaces, we refer the readers to [6–12]. For other references concerned with various fixed point results for one, two, three, or four self-mappings in the setting of metric, ordered metric, partial metric, Prešić-type mappings, cone metric, G-metric spaces, and so forth, we refer the readers to [13–24].

In particular, when \(E = \mathbb{R}\), the partial order defined by (1) is reduced to the one defined by Caristi [2] who denote it by \(\prec_1\). Zhang [25, 26] and Li [27] considered the existence of fixed points of a mapping \(T : X \rightarrow X\) (resp., \(T : X \rightarrow 2^X\)) such that

\[
x_0 \prec_1 T x_0 \quad (\text{resp., } \exists y \in T x_0, \ x_0 \prec_1 y),
\]

for some \(x_0 \in X\), and proved some maximal and minimal fixed point theorems at the expense that \(T\) is monotone with respect to the partial order \(\prec_1\).

In this paper, we shall extend the results of Zhang [25, 26] and Li [27] to the case of cone metric spaces. Some maximal and minimal fixed point theorems of set-valued monotone mappings with respect to the partial order \(<\) are established in cone metric spaces. In addition, not only the existence of maximal and minimal fixed points but also the existence of largest and least fixed points is proved for single-valued increasing mappings. It is worth mentioning that the results
on single-valued mappings in this paper are still new even in the case of metric spaces and hence they indeed improve the results of Zhang [25] and Li [27].

2. Preliminaries

First, we recall some definitions and properties of cones and cone metric spaces; these can be found in [1, 3, 17–24, 28–30].

Let $E$ be a topological vector space. A cone $P$ of $E$ is a nonempty closed subset of $E$ such that $ax + by \in P$ for all $a, b \geq 0$ and $P \cap (-P) = \{0\}$, where $\theta$ is the zero element of $E$. A cone $P$ of $E$ determines a partial order $\leq$ on $E$ by $x \leq y$ if $y - x \in P$ for all $x, y \in E$. For all $x, y \in E$ with $y - x \in \text{int} P$, we write $x \ll y$, where $\text{int} P$ is the interior of $P$.

Let $P$ be a cone of a topological vector space. $P$ is total order minihedral if, for all upper bounded nonempty total order minihedral if, for all lower bounded nonempty set $A$ of a topological vector space $E$.

Remark 2. A total order minihedral cone $P$ of a normed space $E$ is certainly normal see [29].

Let $X$ be a nonempty set and $P$ a cone of a topological vector space $E$. A cone metric [28] is a mapping $d : X \times X \to P$ such that for all $x, y, z \in X$,

\[d(x, y) = \theta\text{ if and only if } x = y,\]
\[d(x, y) = d(y, x),\]
\[d(x, y) \leq d(x, z) + d(z, y).
\]

A pair $(X, d)$ is called a cone metric space over $P$ if $d : X \times X \to P$ is a cone metric. Let $(X, d)$ be a cone metric space over a cone $P$ of a topological vector space $E$. A sequence $\{x_n\}$ in $(X, d)$ converges to $x \in X$ (denote $x_n \xrightarrow{d} x$) if, for all $\varepsilon \in P$ with $\theta \leq \varepsilon$, there exists a positive integer $n_\varepsilon$ such that $d(x_n, x) \ll \varepsilon$ for all $n \geq n_\varepsilon$. A sequence $\{x_n\}$ in $(X, d)$ is Cauchy [28] if, for all $\varepsilon \in P$ with $\theta \leq \varepsilon$, there exists a positive integer $n_\varepsilon$ such that $d(x_m, x_n) \ll \varepsilon$ for all $m, n \geq n_\varepsilon$. A cone metric space $(X, d)$ is complete [28] if all Cauchy sequence $\{x_n\}$ in $(X, d)$ converges to a point $x \in X$. A vector functional $\varphi : X \to E$ is sequentially continuous at some $x \in X$ if $\lim_{n \to \infty} d(x_n, x) = 0$ for all $\{x_n\} \subseteq X$ such that $x_n \xrightarrow{d} x$. If, for all $x \in X$, $\varphi$ is sequentially continuous at $x$, then $\varphi : X \to E$ is sequentially continuous.

Remark 2. Let $(X, d)$ be a cone metric space over a normal cone $P$ of a normed vector space $E$ and $\{x_n\}$ a sequence in $(X, d)$. Then $x_n \xrightarrow{d} x$ if and only if $\lim_{n \to \infty} d(x_n, x) = \theta$, and $\{x_n\}$ is Cauchy if and only if $\lim_{m, n \to \infty} d(x_n, x_m) = \theta$ see [28].

Let $X$ be a nonempty set and $\prec$ a partial order on $X$. For all $x, y \in X$ with $x < y$, set $[x, +\infty) = \{z \in X : x < z\}$, $(-\infty, x) = \{z \in X : z < x\}$, and $[x, y] = \{z \in X : x < z < y\}$. Let $A$ be a nonempty subset of $X$. A set-valued mapping $T : X \to 2^X$ is increasing on $A$ if, for all $x, y \in A$ with $x < y$ and all $\varepsilon \in Ty$, there exists $\varepsilon' \in Tx$ such that $u \ll \varepsilon'$. A set-valued mapping $T : X \to 2^X$ is quasi-increasing if, for all $x, y \in A$ with $x < y$ and all $\varepsilon \in Ty$, there exists $\varepsilon' \in Tx$ such that $u \ll \varepsilon'$.

A point $x^* \in X$ is called a fixed point of a set-valued (resp., single-valued) mapping $T$ if $x^* \in Tx^*$ (resp. $x^* = Tx^*$). Let $A$ be a nonempty subset of $X$ and let $x^* \in A$ be a fixed point of a mapping $T$. $x^*$ is called a maximal (resp. minimal) fixed point of $T$ in $A$ if for all fixed point $x \in A$ of $T$, $x^* < x$ (resp., $x < x^*$) implies $x^* = x$. A largest (resp., least) fixed point of $T$ in $A$ if, for all fixed point $x \in A$ of $T$, $x < x^*$ (resp., $x^* < x$). A largest (resp., least) fixed point of $T$ in $A$ is naturally a maximal (resp., minimal) fixed point in $A$, but the converse may not be true.

3. Fixed Point Theorems

In this section, we always assume that the partial order $\prec$ is defined by (1).

Theorem 3. Let $(X, d, \prec)$ be a complete partially ordered cone metric space over a total order minihedral and continuous cone $P$ of a normed vector space $E$. Let $\varphi : X \to E$ be a sequentially continuous vector functional and let $T : X \to 2^X$ be a set-valued mapping such that $Tx$ is compact for all $x \in X$. Assume that there exists $x_0 \in X$ such that $\varphi$ is bounded below on $[x_0, +\infty)$, $T$ is increasing on $[x_0, +\infty)$, and $T(x_0) \cap [x_0, +\infty) \neq \emptyset$. Then $T$ has a maximal fixed point $x^* \in [x_0, +\infty)$.

Proof. Since $P$ is a total order minihedral cone and $E$ is a normed space, then $P$ is a normal cone by Remark 1. Set

$$Q_1 = \{x \in [x_0, +\infty) : Tx \cap [x, +\infty) \neq \emptyset\}. \quad (4)$$

Clearly, $Q_1$ is nonempty since $x_0 \in Q_1$. Let $\{x_n\}_{n \in \Gamma} \subseteq Q_1$ be an increasing chain, where $\Gamma$ is a directed set. Then by (1) we have

$$d(x_\alpha, x_\beta) \leq \varphi(x_\alpha) - \varphi(x_\beta), \quad (5)$$

for all $\alpha, \beta \in \Gamma$ with $\alpha \leq \beta$. This implies that $\{\varphi(x_\alpha)\}$ is a decreasing chain in $E$. Since $P$ is total order minihedral and $\varphi$ is bounded below on $[x_0, +\infty)$, then $\inf_{\alpha \in \Gamma} \varphi(x_\alpha)$ exists in $E$. Moreover, $\inf_{\alpha \in \Gamma} \varphi(x_\alpha) = \inf_{\alpha \in \Gamma} \varphi(x_\alpha)$ exists in $E$. Since $P$ is continuous. Therefore there exists an increasing sequence $\{x_\alpha\} \subseteq [x_0]$ such that $\lim_{n \to +\infty} \varphi(x_\alpha) = \inf_{\alpha \in \Gamma} \varphi(x_\alpha)$, i.e.,

$$\lim_{n \to +\infty} \varphi(x_\alpha) = \inf_{\alpha \in \Gamma} \varphi(x_\alpha). \quad (6)$$
By (1) we have for all \( m \in \mathbb{N} \) such that \( m \geq n \),
\[
d\left(x_{n}, x_{m}\right) \leq \varphi\left(x_{n}\right) - \varphi\left(x_{m}\right).
\] (7)

Let \( n \to \infty \), by (6) we have \( \lim_{m \to \infty} \left[\varphi\left(x_{n}\right) - \varphi\left(x_{m}\right)\right] = \theta \) and hence \( \lim_{m \to \infty} d\left(x_{n}, x_{m}\right) = \theta \) by the normality of \( P \). Moreover by (10)
\[
\lim_{n \to \infty} \left[\varphi\left(x_{n}\right) - \varphi\left(x_{m}\right)\right] = \theta
\]
and hence \( \lim_{n \to \infty} d\left(x_{n}, x_{m}\right) = \theta \) by the normality of \( P \). Moreover by the
increasing property of \( T \) on \([x_0, +\infty)\), there exists \( x^* \in Tx^* \) such that \( y^* < x^* \). Moreover by the increasing property of \( T \) on \([x_0, +\infty)\), there exists \( z^* \in Tx^* \) such that \( z^* < x^* \). This indicates \( z^* \in Tx^* \cap [x^*, +\infty) \) and hence \( z^* \in Q_1 \). Finally the
maximality of \( x^* \) in \( Q_1 \) forces that \( x^* = z^* \in Tx^* \); that is, \( x^* \) is a maximal fixed point of \( T \) in \([x_0, +\infty)\). The proof is complete.

**Theorem 4.** Let \((X, d, <)\) be a complete partially ordered cone metric space over a total order minihedral cone \(P\) of a normed vector space \(E\). Let \( \varphi: X \to E \) be a sequentially continuous vector function and \( T: X \to 2^X \) be a set-valued mapping such that \( Tx \) is compact for all \( x \in X \). Assume that there exists \( y_0 \in X \) such that \( \varphi \) is bounded above on \((−\infty, y_0]\), \( T \) is quasi-increasing on \((−\infty, y_0]\), and \( T y_0 \cap (−\infty, y_0] \neq \emptyset \). Then \( T \) has a minimal fixed point \( x_* \in (−\infty, y_0] \).

**Proof.** Set
\[
Q_2 = \left\{ x \in (−\infty, y_0] : Tx \cap (−\infty, x] \neq \emptyset \right\}.
\] (17)
Clearly, \( Q_2 \neq \emptyset \). By the same method used in the proof of Theorem 3, we can prove that \((Q_2, \langle \rangle, <)\) has a minimal element \( x_* \) which is also a minimal fixed point of \( T \) in \((−\infty, y_0]\). The proof is complete.

**Remark 5.** If \( T: X \to X \) is a single-valued mapping, then \( Tx \) is naturally compact for all \( x \in X \). Hence both of Theorems 3 and 4 are still valid for a single-valued mapping.

In particular when \( T \) is a single-valued mapping, we have the following further results.

**Theorem 6.** Let \((X, d, <)\) be a complete partially ordered cone metric space over a total order minihedral and continuous cone \(P\) of a normed vector space \(E\). Let \( \varphi: X \to E \) be a sequentially continuous vector function and \( T: X \to 2^X \) be a single-valued mapping. Assume that there exists \( x_0 \in X \) such that \( \varphi \) is bounded below on \([x_0, +\infty)\), \( T \) is increasing on \([x_0, +\infty)\), and \( x_0 \in Tx_0 \). Then \( T \) has a maximal fixed point \( x^* \) and a least fixed point \( x_* \) in \([x_0, +\infty)\) such that \( x_* \prec x^* \).

**Proof.** By Theorem 3 and Remark 5, \( T \) has a maximal fixed point \( x^* \in [x_0, +\infty) \) and hence \( F = \{ x \in [x_0, +\infty) : x = Tx \} \neq \emptyset \). Set
\[
S = \left\{ I = [x, +\infty) : x \in [x_0, +\infty), x \in Tx, F \subseteq I \right\}.
\] (18)
Clearly, \([x_0, +\infty) \in S \) and hence \( S \neq \emptyset \). Define a relation \( \equiv \) on \( S \) by
\[
I_1 \equiv I_2 \iff I_1 \subseteq I_2,
\] (19)
for all \( I_1, I_2 \in S \), then it is easy to check that \( \equiv \) is a partial order on \( S \).
Let \( \{I\alpha\}_{\alpha \in \Gamma} \) be a decreasing chain of \( S \), where \( I\alpha = [x\alpha, +\infty) \). From (1), (18), and (19) we find that \( \{x\alpha\}_{\alpha \in \Gamma} \) is an increasing chain of \( M \), where

\[
M = \{x \in [x_0, +\infty): x < Tx, F \subseteq [x, +\infty]\}. 
\]

Set \( \overline{Q}_1 = \{x \in [x_0, +\infty): x < Tx\} \). Clearly, \( M \subseteq \overline{Q}_1 \). Following the proof of Theorem 3, there exists \( \overline{x} \in \overline{Q}_1 \) and an increasing sequence \( \{x\alpha\}_{\alpha \in \Gamma} \subseteq [x\alpha] \) satisfying (6) such that (8) and (11) are satisfied. From \( x\alpha \in M \) we have that \( x\alpha < x \) for all \( x \in F \) and all \( n \). Thus the increasing property of \( T \) on \([x_0, +\infty)\) implies that, for all \( x \in F \) and all \( n \),

\[
x\alpha < Tx\alpha < Tx = x, 
\]

and hence by (1),

\[
d(x\alpha, x) \leq \phi(x\alpha) - \phi(x), 
\]

for all \( x \in F \) and all \( n \). Let \( n \to \infty \), then by (8) and the continuity of \( \phi \) we have \( d(\overline{x}, x) \leq \phi(\overline{x}) - \phi(x) \); that is,

\[
\overline{x} < x, 
\]

for all \( x \in F \). This together with \( \overline{x} \in \overline{Q}_1 \) implies \( \overline{x} \in M \). Then in analogy to the proof of Theorem 3, by (6), (8), and \( \overline{x} \in M \) we can prove \( \{x\alpha\}_{\alpha \in \Gamma} \) has an upper bound \( \overline{x} \in M \). By (18), we have \( \{\overline{x}, +\infty\} \subseteq S \). Note that \( \overline{x} \) is an upper bound of \( \{x\alpha\}_{\alpha \in \Gamma} \in M \), then \([\overline{x}, +\infty) \subseteq I\alpha \) for all \( \alpha \in \Gamma \) and hence by (19),

\[
[\overline{x}, +\infty) \subseteq I\alpha, 
\]

for all \( \alpha \in \Gamma \). This means \([\overline{x}, +\infty) \) is a lower bound of \( \{I\alpha\}_{\alpha \in \Gamma} \) in \( S \). By Zorn’s lemma, \((S, \sqsubseteq)\) has a minimal element; denote it by \( I^* = [x^*, +\infty) \). By (18) we have \( x_0 < x^* < Tx^* \) and

\[
x^* < x, 
\]

for all \( x \in F \). By the increasing property of \( T \), we have \( x_0 < x^* < Tx^* < T(Tx^*) \) and \( Tx^* < Tx = x \) for all \( x \in F \), which implies \([Tx^*, +\infty) \subseteq S \) and \([Tx^*, +\infty) \subseteq I^* \). Moreover by (19), \([Tx^*, +\infty) \subseteq I^* \). The minimality of \( I^* \) in \( S \) forces that \([Tx^*, +\infty) = I^* \) and so we have \( x^* = Tx^* \). Finally, by (25), \( x^* \) is a least fixed point of \( T \) in \([x_0, +\infty) \) and \( x_0 < x^* < x^\ast \). The proof is complete.

Theorem 7. Let \((X, d, \prec)\) be a completely partially ordered cone metric space over a total order minced field and continuous cone \( P \) of a normed vector space \( E \). Let \( \phi: X \to E \) be a sequentially continuous vector functional and let \( T: X \to X \) be a single-valued mapping. Assume that there exists \( x_0 \in X \) such that \( \phi \) is bounded above on \((\infty, y_0) \), \( T \) is increasing on \((\infty, y_0) \), and \( Ty_0 < y_0 \). Then \( T \) has a minimal fixed point \( x^* \) and a largest fixed point in \( x^\ast \) in \((\infty, x_0) \) such that \( x^* < x^\ast \).

Proof. By Theorem 4 and Remark 5, \( T \) has a minimal fixed point in \( x^* \in (\infty, y_0) \). Set

\[
\mathcal{S} = \{I = (\infty, x): x \in (\infty, y_0), Tx < x, F \subseteq L\}. 
\]

Define a relation \( \sqsubseteq \) on \( \mathcal{S} \) as follows:

\[
J_1 \sqsubseteq J_2 \iff J_1 \subseteq J_2, 
\]

for all \( J_1, J_2 \in \mathcal{S} \), then \( \sqsubseteq \) is a partial order on \( \mathcal{S} \). In an analogy to the proof of Theorem 4, we can prove \((\mathcal{S}, \sqsubseteq)\) has a minimal element \((\infty, x^\ast) \) and \( x^\ast \) is a largest fixed point of \( T \) in \((\infty, y_0) \). The proof is complete.

Theorem 8. Let \((X, d, \prec)\) be a completely partially ordered cone metric space over a total order minced field and continuous cone \( P \) of a normed vector space \( E \). Let \( \phi: X \to E \) be a sequentially continuous vector functional and let \( T: X \to X \) be a single-valued mapping. Assume that there exists \( x_0, y_0 \in X \) with \( x_0 < y_0 \) such that \( T \) is increasing on \([x_0, y_0) \) and \( x_0 < Ty_0 < y_0 \). Then \( T \) has a largest fixed point \( x^\ast \) and a least fixed point \( x_\ast \) in \([x_0, y_0) \) such that \( x_\ast < x^\ast \).

Proof. For all \( x \in [x_0, y_0) \), by (1) we have \( \phi(y_0) \leq \phi(x) \); that is, \( \phi \) is bounded on \([x_0, y_0) \). In an analogy to the proof of Theorem 3, we can prove \( T \) has a maximal fixed point and a minimal fixed point in \([x_0, y_0) \) by investigating the existence of maximal element and minimal element, respectively; in \( D_1 = \{x \in [x_0, y_0) : x < Tx\} \) and \( D_2 = \{x \in [x_0, y_0) : Tx < x\} \). Let

\[
S_1 = \{I = [x, y): x \in [x_0, y_0), x < Tx, G \subseteq I\}, 
\]

\[
S_2 = \{I = [x, y): x \in [x_0, y_0), Tx < x, G \subseteq J\}, 
\]

where \( G = \{x \in [x_0, y_0) : Tx = x\} \) is nonempty. Define \( \sqsubseteq_1 \) on \( S_1 \) and \( \sqsubseteq_2 \) on \( S_2 \), respectively, by

\[
I_1 \sqsubseteq_1 I_2 \iff I_1 \subseteq I_2, \quad \forall I_1, I_2 \in S_1, 
\]

\[
I_1 \sqsubseteq_2 I_2 \iff I_1 \subseteq I_2, \quad \forall I_1, I_2 \in S_2, 
\]

then it is easy to check that \( \sqsubseteq_1 \) and \( \sqsubseteq_2 \) are partial orders on \( S_1 \) and \( S_2 \), respectively. In an analogy to the proof of Theorem 4, we can prove \((S_1, \sqsubseteq_1)\) has a minimal element \( I_\ast = [x_\ast, y_\ast) \) and \((S_2, \sqsubseteq_2)\) has a minimal element \( I^* = [x^*, y^*) \). By the definitions of \( S_1 \) and \( S_2 \), we have \( x_\ast, y^* \in [x_0, y_0) \),

\[
x_\ast < x < y^*, 
\]

\[
x_\ast < Tx_\ast < Ty^* < y^*. 
\]

Moreover by (30) and the increasing property of \( T \) on \([x_0, y_0) \), for all \( x \in G \), we have

\[
x_0 < Tx_\ast < x < Ty^* < Ty_0 < y_0, 
\]

and so by (31),

\[
x_\ast < Tx_\ast < T(Tx_\ast) < T(Ty^*) < Ty^* < y^*. 
\]

From (32) and (33) we have that \([Tx_\ast, y_\ast) \subseteq S_1, [Tx^*, y^*) \subseteq S_2 \), and

\[
[Tx^*, y_0) \sqsubseteq_1 I^*, \quad [x_0, Ty^*) \sqsubseteq_2 I^*, 
\]

which implies \([Tx_\ast, y_\ast) = I_\ast \) and \([x_0, Ty^*) = I^* \) by the minimality of \( I_\ast \) and \( I^* \). This means that \( Tx_\ast = x_\ast \) and \( Ty^* = y^* \). Hence \( x_\ast \) is the least fixed point and \( y^* \) is the largest fixed point of \( T \) in \([x_0, y_0) \) by (31). The proof is complete.
Remark 9. Theorems 3–8 are extensions of [4, Theorems 3 and 4] and [2, Theorems 3, 4, and 5] to the case of cone metric spaces. It is worth mentioning that in Theorems 4, 7, and 8, not only the existence of maximal and minimal fixed points but also the existence of largest and least fixed points is obtained. Therefore Theorems 4, 7, and 8 are still new even in the case of metric space and hence they indeed improve [2, Theorems 3, 4, and 6].

Now we give an example to demonstrate Theorem 3.

Example 10. Let $X = \{1, 2, 3, 4\}$, $E = \mathbb{R}^2$ with the norm $\|u\| = \sqrt{u_1^2 + u_2^2}$ for all $u = (u_1, u_2) \in \mathbb{R}^2$ and $P = \mathbb{R}^2_+$. Clearly, $P$ is a strongly minihedral and continuous cone of $E$. Define a mapping $d : \mathbb{R} \times \mathbb{R} \to P$ by

$$d(x, y) = \left( |x - y|, \frac{|x - y|^{1/2}}{|x|} \right), \quad \forall x, y \in \mathbb{R},$$

then $(\mathbb{R}, d)$ is a complete cone metric space over $P$ and hence $(X, d)$ is a complete cone metric subspace of $(\mathbb{R}, d)$. Define a vector functional $\varphi : [1, +\infty) \to E$ by

$$\varphi(x) = \left( \frac{6}{x}, \frac{3 \sqrt{2} + 2 \sqrt{3}}{\sqrt{x}} \right),$$

for all $x \in [1, +\infty)$. For arbitrary $x \in [1, +\infty)$, let $\{x_n\} \subseteq [1, +\infty)$ be a sequence such that $x_n \to x$, then $x_n \to x$ and hence $\|\varphi(x_n) - \varphi(x)\| \to 0$, that is, $\lim_{n \to +\infty} \varphi(x_n) = \varphi(x)$. This means that $\varphi : [1, +\infty) \to E$ is sequentially continuous; in particular, $\varphi : X \to E$ is sequentially continuous. From (35) and (36) it is easy to check that

$$1 < 1, \quad 1 < 2, \quad 1 < 3, \quad 1 < 4,$$
$$2 < 2, \quad 2 < 3, \quad 2 < 4,$$
$$3 < 3, \quad 3 < 4, \quad 4 < 4, \quad 4 < 3,$$

where $<$ is the partial order defined by (1). Let $T : X \to 2^X$ be a set-valued mapping such that

$$T1 = \{3, 4\}, \quad T2 = \{1, 3\},$$
$$T3 = \{1, 2, 3, 4\}, \quad T4 = \{1, 2, 3\}.$$

Fix $x_0 = 2$, then $[x_0, +\infty) = \{x \in X : 2 < x\} = \{2, 3, 4\}$ by (37), and so $T x_0 \cap [x_0, +\infty) = \{3\} \neq \emptyset$. For $x \in [x_0, +\infty)$, if $x < y$ and $x \neq y$, then we have only two cases: $x = 2 < 3 = y$ and $x = 2 < 4 = y$ by (37). Fix $x = 2$ and $y = 3$, then $v = 3, 4 \in Ty$ such that $u < v$. Fix $x = 2$ and $y = 4$, then $u = 3, 4 \in Ty$ such that $u < v$. This means that $T : X \to 2^X$ is increasing on $[x_0, +\infty)$. Therefore all the conditions of Theorem 3 are satisfied and hence $T$ has a fixed point $3 \in [x_0, +\infty)$.

Fix $x = 4$; for all $y \in T4$, we have $x = 4 \neq y$ by (37); that is, (2) is not satisfied. Therefore the existence of fixed points could not be obtained by generalized Caristi’s fixed point theorems in cone metric spaces of $[1, 3]$.

Acknowledgments

The work was supported by Natural Science Foundation of China (11161022), Natural Science Foundation of Jiangxi Province (2014BAB21006, 20122BAB201015), Educational Department of Jiangxi Province (GJJ12280), and Program for Excellent Youth Talents of JXUF (201201). The authors are grateful to the editor and referees for their critical suggestions led to the improvement of the presentation of the work.
