An SI epidemic model with stage structure is investigated. In the model, impulsive biological control is taken, that is, we release infected pests to the field at a fixed time periodically. We get a sufficient condition for the global asymptotical stability of the pest-eradication periodic solution \((0, 0, \tilde{I}(t))\), and a condition for the permanence of the system. At last, a brief discussion shows that our results will be helpful for pest management.

1. Introduction

According to reports of Food and Agriculture Organization of the United Nations, the warfare between human and pests (such as locust, Aphis, cotton bollworm, etc.) has sustained for thousands of years. With the development of society and the progress of science and technology, man has adopted some advanced and modern weapons such as chemical pesticides, biological pesticides, remote sensing and measuring, computers, atomic energy, and so on. At last, some brilliant achievements have been obtained [1–4]. However, the warfare is not over, and will continue. A great deal of, and a large variety of, pesticides were used to control pests. In all, pesticides are useful because they can quickly kill a significant portion of a pest population and sometimes provide the only feasible method for preventing economic loss. However, pesticide pollution is also recognized as a major health hazard to human beings and beneficial insects. Biological control is, man’s use of a suitably chosen living organism, referred as the biological control agent, to control another. Biological control agents can be predators, pathogens or parasites of the organism to be controlled that either kill the harmful organism or interfere with its biological progress. There is a vast amount of literatures on the applications of microbial disease to
suppress pests [1–3], but there are a few papers on the mathematical model of the
dynamical of microbial disease in pest control [4–7]. The use of bacteria, fungi, and viruses
is potentially one of the most important approaches in pest control. For example, Asian
tiger mosquito (Aedes albopictus) can transmit viruses which cause dengue fever, Ross
River fever, or Japanese encephalitis. To avoid this and to control the spread of mosquito
swarms, we could spray with Bt, which is a variety of the bacterium Bacillus thuringiensis
(Bt). An advantage of using insect pathogens is that they are safer to man and are usually
safer to beneficial insects. In this paper, our aim is to control pests.

Impulsive equations are adequate to model processes with abrupt changes. Especially,
impulsive differential equations can describe population dynamic models, since many life
phenomena and human exploitation are almost impulsive in the natural world. (Some
recent and general references on the theory of impulsive equations are [8–16].) There are
also many applications of impulsive equations [17–25].

Stage structure is an important notation in epidemiology and demography because
there are some kinds of diseases which are only spread or have more opportunities to
be spread in children, for example, measles, mumps, chickenpox, scarlet fever, and diph-
theria, while other infectious diseases such as gonorrhea and syphilis are spread only in
adults. There are literatures about single species with stage structure [26, 27], while oth-
ers are about competitive or predator-prey systems with stage structure [28–31]. There
are still other models with stage structure [27, 32–36]. In this paper, we consider the case
in which the disease spreads only in mature pests, while the immature pests cannot be in-
fected, for the immature are protected by their eggshells. For the purpose of pests control,
we take biological control measures, that is, we release infected pests impulsively to the
field, then more of the pests will be infected and die. The infected pests may be cultivated
artificially in laboratory.

Xiao and Chen [34, 36] have studied SIS models with stage structure, but they did
not consider the effects of impulse. To our knowledge, there are few papers about stage-
structured models with impulse interruption (see [7]). The present paper constructs and
analyzes a realistic model of impulsive biological control system for pest management.
The paper is organized as follows. In Section 2, the main biological assumptions are for-
mulated, and the model is constructed. In Section 3, by use of the Floquet theory for
impulsive differential equations, the small-amplitude perturbation method and compar-
ison techniques, we get the sufficient condition for the global asymptotic stability of the
pest-eradication periodic solution and also the sufficient condition for the permanence
of the system. Finally, a brief discussion is provided in the last section.

2. Model formulation

The basic stage-structured SI model is

\begin{align}
S_1'(t) &= rS_2(t) - \mu S_1(t) - \delta S_1(t), \\
S_2'(t) &= \delta S_1(t) - \mu S_2(t) - S_2^2(t) - \beta S_2(t)I(t), \\
I'(t) &= \beta S_2(t)I(t) - (\mu + \alpha)I(t),
\end{align}

(2.1)
where $S_2(t)$ and $I(t)$ denote the densities of susceptible and infected mature populations, respectively, and $S_1(t)$ denotes the density of an immature population which does not contract the disease. All coefficients are positive constants. The models are derived with the following assumptions.

(H1) All newborns are assumed to be susceptible. We assume that at any time $t > 0$, birth into the immature population is proportional to the existing mature susceptible, with proportionality $r$, and the infected mature population does not have offsprings.

(H2) The immature susceptible population has the natural death rate $\mu$. The death rate of the mature susceptible population is proportional both to the existing mature population and to the square of it with proportionality constants $\mu$ and 1. The infected mature population has the natural death rate $\mu$ and an extra disease-related death rate $\alpha$.

(H3) The immature population enters into mature susceptible with proportionality constant $\delta$.

(H4) It is assumed that the incidence rate is double linear $\beta S_2(t) I(t)$, that is, the rate at which the susceptible mature becomes infected.

In this paper, with an additional assumption (H5), we construct the following model, and the parameters are the same as those in system (2.1).

(H5) We release an infected mature population with constant number $p > 0$ periodically with period $\tau > 0$;

\[
\begin{aligned}
S'_1(t) &= r S_2(t) - \mu S_1(t) - \delta S_1(t), \quad t \neq n \tau, n = 1, 2, 3, \ldots, \\
S'_2(t) &= \delta S_1(t) - \mu S_2(t) - S_2^2(t) - \beta S_2(t) I(t), \quad t \neq n \tau, n = 1, 2, 3, \ldots,
\end{aligned}
\]

\[
I'(t) = \beta S_2(t) I(t) - (\mu + \alpha) I(t), \quad t \neq n \tau, n = 1, 2, 3, \ldots,
\]

\[
\Delta S_1(t) = 0, \quad \Delta S_2(t) = 0, \quad \Delta I(t) = p, \quad t = n \tau, n = 1, 2, 3, \ldots.
\]

3. Qualitative analysis for system (2.2)

In this section, we will study the effect of impulsive releasing of infected pests to the original model (2.1). To prove our main results, we give the following definition and lemmas.

**Definition 3.1.** System (2.2) is said to be permanent if there are constants $m, M > 0$ (independent of the initial value), and a finite time $T_0$ such that for all solutions $(S_1(t), S_2(t), I(t))$ with initial values $S_1(0^+) > 0, S_2(0^+) > 0, I(0^+) > 0, m \leq S_1(t) + S_2(t) \leq M$, and $m \leq I(t) \leq M$ hold for all $t \geq T_0$. Here, $T_0$ may depend on the initial values $(S_1(0^+), S_2(0^+), I(0^+))$.

**Lemma 3.2** (see [8, 9]). Suppose $(S_1(t), S_2(t), I(t))$ is a solution of system (2.2) with initial values $S_1(0^+) \geq 0, S_2(0^+) \geq 0$, and $I(0^+) \geq 0$. Then $S_1(t) \geq 0, S_2(t) \geq 0$, and $I(t) \geq 0$ for all $t \geq 0$. And further, $S_1(t) > 0, S_2(t) > 0$, and $I(t) > 0$ if $S_1(0^+) > 0, S_2(0^+) > 0$, and $I(0^+) > 0$.

**Lemma 3.3** (see [9]). Let the function $m \in pC'[\mathbb{R}^+, \mathbb{R}]$ satisfy the inequalities

\[
m'(t) \leq p(t) m(t) + q(t), \quad t \geq t_0, t \neq t_k, k = 1, 2, \ldots,
\]

\[
m(t_k^+) \leq d_k m(t_k) + b_k, \quad t = t_k,
\]

(3.1)
where \( p, q \in PC[\mathbb{R}^+, \mathbb{R}] \), and \( d_k \geq 0, b_k \) are constants. Then

\[
m(t) \leq m(t_0) \left( \prod_{t_0 < t < t} d_k \right) e^{\int_{t_0}^{t} p(s) \, ds} + \sum_{t_0 < t < t} b_k \left( \prod_{t_0 < t < t} d_j \right) e^{\int_{t_0}^{t} p(s) \, ds} + \int_{t_0}^{t} \left( \prod_{s < t < t} d_k \right) e^{\int_{s}^{t} p(s) \, ds} \, q(s) \, ds,
\]

for all \( t \geq t_0 \).

If \( S_1(t) = S_2(t) = 0 \), we have the following subsystem of system (2.2):

\[
I'(t) = - (\mu + \alpha) I(t), \quad t \neq n\tau, \quad n = 1, 2, \ldots
\]

\[
I(n\tau^+) = I(n\tau) + p, \quad t = n\tau, \quad n = 1, 2, \ldots \tag{3.3}
\]

Obviously, \( I(t) = pe^{-(\mu+\alpha)(t-n\tau)}/(1-e^{-\mu\tau}), t \in (n\tau, (n+1)\tau], n \in \mathbb{Z}_+, T(0+) = \mu/(1-e^{-(\mu+\alpha)t}) \), is a positive periodic solution of system (3.3). Therefore, the complete expression for the pest-eradication periodic solution of system (2.2) is obtained as \( (0,0,\tilde{T}(t)) = (0,0,pe^{-(\mu+\alpha)(t-n\tau)}/(1-e^{-(\mu+\alpha)t})), t \in (n\tau, (n+1)\tau], n \in \mathbb{Z}_+ \). Since the solution of system (3.3) is \( I(t) = (I(0^+) - p/(1-e^{-(\mu+\alpha)t})) e^{-(\mu+\alpha)t} + \tilde{T}(t) \), \( t \in (n\tau, (n+1)\tau], n \in \mathbb{Z}_+ \), so we derive the following.

**Lemma 3.4** (see [8]). For every solution of system (3.3) with initial condition \( I(0^+) > 0 \), it follows that \( I(t) - \tilde{T}(t) \) as \( t \to \infty \).

**Lemma 3.5.** There exists a constant \( M > 0 \) such that \( S_1(t) \leq M, S_2(t) \leq M, I(t) \leq M \) for each solution \( (S_1(t), S_2(t), I(t)) \) of system (2.2) for all \( t \) large enough (where \( t \) depends on the initial value).

**Proof.** Due to the positivity of \( S_1(t), S_2(t), \) and \( I(t) \), we can select \( U(t) = S_1(t) + S_2(t) + I(t) \) as a Liapunov function.

When \( t \neq n\tau \), we have

\[
D^+ U(t) + \mu U(t) = rS_2(t) - S_2(t) - \alpha I(t)
\leq rS_2(t) - S_2(t) \leq \frac{r^2}{4}. \tag{3.4}
\]

When \( t = n\tau \), \( U(n\tau^+) = U(n\tau) + p \).

By Lemma 3.3, for \( t \in (n\tau, (n+1)\tau] \), we have

\[
U(t) \leq \left( U(0^+) - \frac{r^2}{4\mu} \right) e^{-\mu t} + \frac{p(1-e^{-\eta\mu t})}{1-e^{-\mu t}} e^{-\mu(t-n\tau)} + \frac{r^2}{4\mu}. \tag{3.5}
\]

So \( U(t) \) is uniformly ultimately bounded by a constant, and there exists a constant \( M > 0 \) such that \( S_1(t) \leq M, S_2(t) \leq M, I(t) \leq M \) for each solution \( (S_1(t), S_2(t), I(t)) \) of system (2.2) for all \( t \) large enough. The proof is complete.

In the following, we investigate the stability of the pest eradication periodic solution of system (2.2).
Theorem 3.6. Let \((S_1(t), S_2(t), I(t))\) be any solution of system (2.2) with initial values \(S_1(0^+) > 0, S_2(0^+) > 0,\) and \(I(0^+) > 0,\) then \((0, 0, \tilde{I}(t))\) is locally asymptotically stable, provided that
\[
p > \frac{\tau a b}{\beta},
\]
where \(a = \mu + \alpha > 0,\) \(b = (\delta r - \mu(\mu + \delta))/(\mu + \delta) > 0.
\]

Proof. The local stability of pest-eradication periodic solution may be determined by considering the behaviors of a small amplitude perturbation of the solution. Define \(x(t) = S_1(t),\) \(y(t) = S_2(t),\) \(z(t) = I(t) - \tilde{I}(t),\) then the linearized system of system (2.2) reads as
\[
x'(t) = ry(t) - (\mu + \delta)x(t), \quad t \neq n\tau, n = 1, 2, \ldots,
\]
\[
y'(t) = \delta x(t) - \mu y(t) - \beta \tilde{I}(t)y(t), \quad t \neq n\tau, n = 1, 2, \ldots,
\]
\[
z'(t) = \beta \tilde{I}(t)y(t) - (\mu + \alpha)z(t), \quad t \neq n\tau, n = 1, 2, \ldots,
\]
\[
x(n\tau^+) = x(n\tau), \quad y(n\tau^+) = y(n\tau), \quad z(n\tau^+) = z(n\tau), \quad t = n\tau, n = 1, 2, \ldots.
\]
Let \(\Phi(t)\) be the fundamental solution matrix of system (3.7), then \(\Phi(t)\) must satisfy
\[
\frac{d\Phi(t)}{dt} = \begin{pmatrix}
-(\mu + \delta) & r & 0 \\
\delta & -\mu - \beta \tilde{I}(t) & 0 \\
0 & \beta \tilde{I}(t) & -(\mu + \alpha)
\end{pmatrix}\Phi(t) = A\Phi(t),
\]
and \(\Phi(0) = I,\) the identity matrix. We can easily see that one of the eigenvalues of matrix \(A\) is \(-\mu + \alpha),\) and the other two eigenvalues are determined by the \(2 \times 2\) matrix \(B,\) where
\[
B = \begin{pmatrix}
-(\mu + \delta) & r \\
\delta & -\mu - \beta \tilde{I}(t)
\end{pmatrix}.
\]
Denote the eigenvalues of \(B\) as \(\lambda_1, \lambda_2,\) then we have \(\lambda_1 + \lambda_2 = -(\mu + \delta) - \mu - \beta \tilde{I}(t) < 0,\)
\[
\lambda_1\lambda_2 = (\mu + \delta)(\mu + \beta \tilde{I}(t)) - r\delta = (\mu + \delta)[\mu - r\delta/(\mu + \delta) + \beta \tilde{I}(t)].
\]
Therefore, by the Floquet theorem, \((0, 0, \tilde{I}(t))\) is locally asymptotically stable, provided that
\[
\int_0^{\tau} \left(\mu + \beta \tilde{I}(t) - \frac{r\delta}{\mu + \delta}\right)dt > 0,
\]
that is,
\[
[r\delta - \mu(\mu + \delta)]\tau < \frac{\beta p(\mu + \delta)}{\mu + \alpha}.
\]
When \(R_0 = r\delta/\mu(\mu + \delta) \leq 1,\) the above inequality is satisfied for all \(p > 0;\) when \(R_0 = r\delta/\mu(\mu + \delta) > 1,\) the above inequality equals
\[
p > \frac{\tau ab}{\beta}.
\]
The proof is complete.
Theorem 3.7. If \( R_0 \leq 1 \), or \( R_0 > 1 \), and \( p > (e^{at} - 1)(b/\beta) \), then \((0,0,\tilde{I}(t))\) is globally asymptotically stable for system (2.2).

Proof. Let

\[
f(x) = e^x - 1 - x
\]  
(3.13)

because

\[
f'(x) = e^x - 1 > 0, \text{ whenever } x > 0.
\]  
(3.14)

So we have

\[
e^{at} - 1 > a\tau,
\]

\[
p > \left( e^{at} - 1 \right) \frac{b}{\beta} > a\tau \frac{b}{\beta}.
\]  
(3.15)

By Theorem 3.6, we know that \((0,0,\tilde{I}(t))\) is locally asymptotically stable. In the following, we will prove the global attraction of \((0,0,\tilde{I}(t))\).

Let

\[
V(t) = \delta S_1(t) + (\mu + \delta)S_2(t).
\]  
(3.16)

Then

\[
V'(t)_{(2.2)} = \left[ r\delta - \mu(\mu + \delta) - (\mu + \delta)S_2(t) - \beta(\mu + \delta)I(t) \right]S_2(t).
\]  
(3.17)

When \( R_0 \leq 1 \), we clearly have

\[
V'(t)_{(2.2)} \leq -\beta(\mu + \delta)I(t)S_2(t) < 0, \quad \forall \ t \geq 0,
\]  
(3.18)

so \( V(t) \to 0, S_1(t) \to 0, S_2(t) \to 0 \), as \( t \to +\infty \), and \((0,0,\tilde{I}(t))\) is globally attractive.

When \( R_0 > 1 \) and \( p > (e^{at} - 1)(b/\beta) \), we can select \( \epsilon > 0 \) small enough such that \( p > \left( e^{at} - 1 \right)(b + 2\epsilon)/\beta \).

From system (2.2), we have

\[
I'(t) = \beta S_2(t)I(t) - aI(t) \geq -aI(t), \quad t \neq n\tau, n = 1,2,....
\]

\[
I(n\tau^+) = I(n\tau) + p, \quad t = n\tau, n = 1,2,....
\]  
(3.19)

By Lemmas 3.3 and 3.4, we know that there exists a \( t_1 > 0 \) such that \( I(t) \geq pe^{-at}/(1 - e^{-at}) - \epsilon/\beta \) for all \( t \geq t_1 \).

Thus when \( t \geq t_1 \), we have

\[
V'(t)_{(2.2)} = (\mu + \delta)[b - S_2(t) - \beta I(t)]S_2(t)
\]

\[
\leq -(\mu + \delta)(S_2(t) + \epsilon)S_2(t) < 0.
\]  
(3.20)

So \( V(t) \to 0, S_1(t) \to 0, S_2(t) \to 0, \) and \((0,0,\tilde{I}(t))\) is globally attractive. The proof is complete. \( \Box \)
Theorem 3.8. If $R_0 > 1$ and $0 < p < b(1 - e^{-ar})/\beta$, then system (2.2) is permanent.

Proof. Suppose $(S_1(t), S_2(t), I(t))$ is any solution of system (2.2) with initial values $S_1(0^+) > 0, S_2(0^+) > 0,$ and $I(0^+) > 0$. By Lemmas 3.2 and 3.5, we may assume $S_1(t) \leq M, S_2(t) \leq M,$ and $I(t) \leq M$, for all $t \geq 0$, and $M > b/(1 + \beta)$. Let $m = pe^{-(a+\alpha)t} / (1 - e^{-(a+\alpha)t}) - \epsilon_3 > 0, \epsilon_3 > 0$. From Lemma 3.3, we clearly have $I(t) \geq m$ for all $t$ large enough. We will next find an $m_1 > 0$ such that $S_1(t) + S_2(t) \geq m_1$ for $t$ large enough. We will do it in the following two steps.

Step 1. Since $R_0 > 1$ and $0 < p < b(1 - e^{-at})/\beta$, we can choose $m_2 > 0, \epsilon_1 > 0$ small enough such that

$$0 < p < \frac{(b - m_2 - \epsilon_1)(1 - e^{-(a - \beta m_2)t})}{\beta}.$$  (3.21)

Denote

$$\rho = b - m_2 - \epsilon_1 - \frac{p\beta}{1 - e^{-(a - \beta m_2)t}} > 0,$$  \hspace{1cm} (3.22)

$$\sigma = b - M(1 + \beta) < 0.$$  \hspace{1cm}

Consider the Liapunov function

$$V(t) = \delta S_1(t) + (\mu + \delta)S_2(t).$$  \hspace{1cm} (3.23)

We claim that $V(t) < (\mu + \delta)m_2 = m_3$ cannot hold for all $t \geq 0$. Otherwise, we have that $S_2(t) < m_2$ for all $t \geq 0$. Then, from the third and sixth equations of system (2.2), we get

$$I'(t) \leq (\beta m_2 - a)I(t), \quad t \neq n\tau, n = 1, 2, \ldots,$$

$$I(n\tau^+) = I(n\tau) + p, \quad t = n\tau, n = 1, 2, \ldots.$$  \hspace{1cm} (3.24)

By Lemma 3.3, we know that there exists a $t_1 > 0$ such that $I(t) \leq \overline{u}(t) + \epsilon_1/\beta,$ for all $t \geq t_1,$ and here, $\overline{u}(t) = pe^{-(a - \beta m_2)(t - n\tau)} / (1 - e^{-(a - \beta m_2)t}), t \in (n\tau, (n + 1)\tau], n \in \mathbb{Z}_+. So I(t) \leq p/(1 - e^{-(a - \beta m_2)t}) + \epsilon_1/\beta$, for all $t \geq t_1,$ and

$$V'(t)|_{(2.2)} = (\mu + \delta)[b - S_2(t) - \beta I(t)]S_2(t)$$

$$\geq (\mu + \delta) \left[b - m_2 - \epsilon_1 - \frac{p\beta}{1 - e^{-(a - \beta m_2)t}}\right]S_2(t)$$  \hspace{1cm} (3.25)

$$= \rho(\mu + \delta)S_2(t) > 0$$

for all $t > t_1$. Thus

$$V'(t)|_{(2.2)} \geq \rho(\mu + \delta)S_2(t_1) = \epsilon_2 > 0,$$

$$V(t) \longrightarrow +\infty, \quad S_2(t) \longrightarrow +\infty, \quad as \ t \longrightarrow +\infty.$$  \hspace{1cm} (3.26)

It is a contradiction since $V(t)$ is ultimately bounded by Lemma 3.5. Therefore, there exists $t_1 > 0$ such that $V(t_1) \geq m_3.$
Step 2. If $V(t) \geq m_3$ hold for all $t \geq t_1$, then we can select $m_1 = m_2$, and our aim is obtained. We consider those solutions which leave the region $D = \{(S_1, S_2, I) \in \mathbb{R}_+^3 : V(t) = \delta S_1(t) + (\mu + \delta)S_2(t) < m_3\}$, and reenter it again. Let $t^* = \inf_{t \geq t_1} \{V(t) < m_3\}$. Then $V(t) \geq m_3$ for $t \in [t_1, t^*)$, and $V(t^*) = m_3$. Suppose $t^* \in [n_1\tau, (n_1 + 1)\tau), n_1 \in \mathbb{N}$. Select $n_2, n_3$ such that

$$n_2\tau > T_2 = -\frac{1}{a - \beta m_2} \ln \frac{\epsilon_1}{M + \rho},$$

$$n_3\tau > T_3 = \frac{m_3}{\rho},$$

$$\rho_1 = \rho(\mu + \delta)S_2((n_1 + 1 + n_2)\tau^+).$$

Let $T = (n_2 + n_3)\tau$. We claim that there must be a $t_2 \in [(n_1 + 1)\tau, (n_1 + 1)\tau + T]$ such that $V(t_2) \geq m_3$. Otherwise, $V(t) < m_3$ and $S_2(t) < m_2$, for all $t \in [(n_1 + 1)\tau, (n_1 + 1)\tau + T]$. Consider

$$u'(t) \leq (\beta m_2 - a)u(t), \quad t \neq n\tau, n = n_1 + 1, n_1 + 2, \ldots,$$

$$u(n\tau^+) = u(n\tau) + \rho, \quad t = n\tau, n = n_1 + 1, n_1 + 2, \ldots,$$

$$u((n_1 + 1)\tau^+) = I((n_1 + 1)\tau^+).$$

By Lemmas 3.3 and 3.4, we have

$$u(t) = \left(u((n_1 + 1)\tau^+) - \frac{\rho}{1 - e^{-(a-\beta m_2)\tau}}\right) e^{-(a-\beta m_2)(t-(n_1 + 1)\tau)} + \overline{u}(t) \quad (3.29)$$

for $t \in (n\tau, (n + 1)\tau]$, $n_1 + 1 \leq n \leq n_1 + 1 + n_2 + n_3$. Then

$$|u(t) - \overline{u}(t)| \leq (M + \rho)e^{-(a-\beta m_2)n_2\tau} < \epsilon_1, \quad (3.30)$$

and by the comparison principle, we have

$$I(t) \leq u(t) \leq \overline{u}(t) + \frac{\epsilon_1}{\beta} \leq \frac{\rho}{1 - e^{-(a-\beta m_2)\tau}} + \frac{\epsilon_1}{\beta} \quad (3.31)$$

for $(n_1 + 1 + n_2)\tau \leq t \leq (n_1 + 1)\tau + T$, which imply that

$$V'(t)_{(2,2)} \geq \rho(\mu + \delta)S_2((n_1 + 1 + n_2)\tau^+) = \rho_1 > 0,$$

$$V((n_1 + 1)\tau + T) \geq V((n_1 + 1 + n_2)\tau^+) + \rho_1 n_3\tau. \quad (3.32)$$

When $t \in [t^*, (n_1 + 1 + n_2)\tau]$, we have

$$V'(t)_{(2,2)} = [r\delta - \mu(\mu + \delta) - (\mu + \delta)S_2(t) - \beta(\mu + \delta)I(t)]S_2(t)$$

$$\geq (\mu + \delta)[b - M - \beta M]S_2(t)$$

$$\geq (\mu + \delta)\sigma S_2(t) \geq \sigma V(t). \quad (3.33)$$
Thus
\[
V((n_1 + 1 + n_2)\tau) \geq V(t^*) e^{\alpha(n_2+1)\tau} > 0,
\]
\[
V((n_1 + 1)\tau + T) \geq V((n_1 + 1 + n_2)\tau) + \rho_1 n_3 \tau > m_3.
\]
(3.34)

It is a contradiction. Let \( \bar{t} = \inf_{t \geq t^*} \{ V(t) \geq m_3 \} \). Then \( V(\bar{t}) \geq m_3 \). For \( t \in [t^*, \bar{t}] \), we have
\[
V(t) \geq V(t^*) e^{\alpha(t-t^*)} \geq m_3 e^{\alpha(1+n_1+n_2+n_3)} = m_4.
\]
(3.35)

For \( t > \bar{t} \), the same arguments can be continued since \( V(\bar{t}) \geq m_3 \). We can select \( m_1 = m_4/\mu \), and \( S_1(t) + S_2(t) \geq m_1 \) for all \( t \geq t_1 \). The proof is complete. \( \square \)

Remark 3.9. From Theorem 3.8, we can see that if the coefficients satisfy the condition \( R_0 > 1 \), then, without control of releasing infected pests, or the releasing number \( p < (1 - e^{-\alpha \tau})(b/\beta) \), the pests will be permanent and they will do harm to the crops. Under this condition, we can increase the releasing amount until \( p > (e^{\alpha \tau} - 1)(b/\beta) \), and by Theorem 3.7, we know that the pests will be doomed.

4. Discussion

In this paper, a stage-structured SI epidemic model is investigated. In the model, impulsive biological control is taken into consideration, and we analyzed the existence and stability of the pest-eradication periodic solution of the system. We also get a sufficient condition for the permanence of the system. In the real world, we can take impulsive biological control to constrain the pest population. There is still an interesting problem: if \( R_0 > 1 \) and \( 0 < p < b(1 - e^{-\alpha \tau})(b/\beta) \), then the system is permanent; if \( R_0 > 1 \) and \( p > (e^{\alpha \tau} - 1)(b/\beta) \), then \((0,0,\tilde{I}(t))\) is globally asymptotically stable. But we have not considered the case that \( R_0 > 1 \) and \( b(1 - e^{-\alpha \tau})/\beta < p < (e^{\alpha \tau} - 1)(b/\beta) \), how about the dynamical behaviors of the system? In this paper, our aim is to control the pest population, so we omit the above problems. But from a mathematical aspect, it is very interesting, and we leave it as a future work.

Acknowledgments

The authors thank the referees very much for their valuable comments and suggestions. This research is supported by National Natural Science Foundation of China (Grant no. 10471117).

References

As a multidisciplinary field, financial engineering is becoming increasingly important in today’s economic and financial world, especially in areas such as portfolio management, asset valuation and prediction, fraud detection, and credit risk management. For example, in a credit risk context, the recently approved Basel II guidelines advise financial institutions to build comprehensible credit risk models in order to optimize their capital allocation policy. Computational methods are being intensively studied and applied to improve the quality of the financial decisions that need to be made. Until now, computational methods and models are central to the analysis of economic and financial decisions.

However, more and more researchers have found that the financial environment is not ruled by mathematical distributions or statistical models. In such situations, some attempts have also been made to develop financial engineering models using intelligent computing approaches. For example, an artificial neural network (ANN) is a nonparametric estimation technique which does not make any distributional assumptions regarding the underlying asset. Instead, ANN approach develops a model using sets of unknown parameters and lets the optimization routine seek the best fitting parameters to obtain the desired results. The main aim of this special issue is not to merely illustrate the superior performance of a new intelligent computational method, but also to demonstrate how it can be used effectively in a financial engineering environment to improve and facilitate financial decision making. In this sense, the submissions should especially address how the results of estimated computational models (e.g., ANN, support vector machines, evolutionary algorithm, and fuzzy models) can be used to develop intelligent, easy-to-use, and/or comprehensible computational systems (e.g., decision support systems, agent-based system, and web-based systems).

This special issue will include (but not be limited to) the following topics:

- **Computational methods:** artificial intelligence, neural networks, evolutionary algorithms, fuzzy inference, hybrid learning, ensemble learning, cooperative learning, multiagent learning
- **Application fields:** asset valuation and prediction, asset allocation and portfolio selection, bankruptcy prediction, fraud detection, credit risk management
- **Implementation aspects:** decision support systems, expert systems, information systems, intelligent agents, web service, monitoring, deployment, implementation

Authors should follow the Journal of Applied Mathematics and Decision Sciences manuscript format described at the journal site http://www.hindawi.com/journals/jamds/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/, according to the following timetable:
