This paper is mainly concerned with the globally exponential stability in mean square of uncertain neutral stochastic systems with mixed delays and Markovian jumping parameters. The mixed delays are comprised of the discrete interval time-varying delays and the distributed time delays. Taking the stochastic perturbation and Markovian jumping parameters into account, some delay-dependent sufficient conditions for the globally exponential stability in mean square of such systems can be obtained by constructing an appropriate Lyapunov-Krasovskii functional, which are given in the form of linear matrix inequalities (LMIs). The derived criteria are dependent on the upper bound and the lower bound of the time-varying delay and the distributed delay and are therefore less conservative. Two numerical examples are given to illustrate the effectiveness and applicability of our obtained results.

1. Introduction

It is well known that many dynamical systems not only depend on the present and past states but also involve the derivative with delays as well as the functional of the past history. Neutral delay differential equations are often used to describe the following systems [1]:

\[
\frac{d[x(t) - Dx(t - \tau) - f(t, x(t), x(t - \tau))]}{dt} = 0.
\] (1.1)

Many authors have considered the dynamical analysis of the neutral delay differential equations (see [2–7] and references therein). For example, Chen et al. in [3] and Wu et al. in [4, 5] have given some LMI-based conditions ensuring the stability analysis and the
stabilization of neutral delay systems. Taking the environmental disturbances into account, the neutral stochastic delay differential equations can be given as follows:

\[ d[x(t) - Dx(t - \tau)] = f(t, x(t), x(t - \tau))dt + g(t, x(t), x(t - \tau))dB(t). \] (1.2)

Some fundamental theories of neutral stochastic delay differential equations are introduced in [1, 8]. Since they can be extensively applied into many branches for the control field, the problem about the exponential stability and the asymptotical stability of the neutral stochastic delay systems has attracted many authors’ attention over the past few years, and many less conservative results of delay-dependent conditions ensuring the stabilization analysis and \( H_\infty \) filtering design for such systems have been reported in many works, see, for example, [9–14] and references therein. The methods used include the Razumikhin-type theorems [10], the Lyapunov functional [13], the fixed point theorem [14], and the linear matrix inequality [9, 11, 12]. For example, Huang and Mao in [9] and Chen et al. in [11] have given the exponential stability criteria of neutral stochastic delay systems. Some LMI-based sufficient conditions for the mean-square exponential stability analysis of stochastic systems of neutral type have been obtained by introducing an auxiliary vector in [12]. In practice, the parameter uncertainty is considered as one of the main sources leading to undesirable behavior (e.g., instability) of dynamical systems, especially when implementing neural networks in applications. The stability analysis of the uncertain neutral stochastic system has received considerable research attention, see, for example, [15–18], and the problem of the \( H_\infty \) filter design of the uncertain neutral stochastic delay systems has been discussed in [19, 20].

On the other hand, Markovian jump systems introduced by [21] are the hybrid systems with two components in the state. The first one refers to the mode that is described by a continuous-time finite-state Markovian process, and the second one refers to the state that is represented by a system of differential equations. The jump systems have the advantage of modeling the dynamic systems subject to abrupt variation in their structures, such as component failures or repairs, sudden environmental disturbance, changing subsystem interconnections, and operating in different points of a nonlinear plant [22]. The stability analysis and \( H_\infty \) filter design of stochastic delay systems with Markovian jumping parameters and delay systems with Markovian jumping parameters have been widely studied, see, for example, [23–38]. For example, in [24], Liu et al. have discussed the exponential stability of delayed recurrent neural networks with Markovian jumping parameters; Liu et al. in [24] and Wang et al. in [25] have considered some sufficient conditions for the exponential stability of stochastic neural networks with mixed time delays and Markovian switching; Mao in [13] has also given some sufficient conditions for the exponential stability of stochastic delay interval systems with Markovian switching. More recently, He and Liu in [39] and Balasubramaniam et al. in [40] have presented some LMI-based sufficient conditions for the exponential stability of uncertain neutral systems with Markovian jumping parameters. Although Kolmanovskii et al. in [17], and Mao et al. in [18] have derived the exponential stability of the neutral stochastic delay systems with Markovian jumping parameters, some sufficient conditions obtained by using the estimate method are not easily checked. Thus, the problem of the stability analysis of the uncertain neutral stochastic systems with mixed delays and Markovian jumping parameters has not been fully investigated and there is still much room left for further consideration, which constitutes the motivation for the present research.
In this paper, the global exponential stability of a class of the uncertain neutral stochastic systems with mixed delays and Markovian jumping parameters is discussed. The delays include the discrete and distributed time delays, and the jumping parameters are generated from a finite state Markov chain. By constructing an appropriate Lyapunov functional, some LMIs-based sufficient conditions ensuring the exponential stability in mean square of the uncertain neutral stochastic systems with mixed delays and Markovian jumping parameters are obtained by using the stochastic analysis and some bounding technique. It is worth pointing out that compared with the earlier works in [17, 18], the obtained results given in the form of the linear matrix inequalities (LMIs) can be easily be solved by using the standard software packages. Two illustrative examples are exploited to demonstrate the effectiveness and applicability of the obtained results.

The content of the paper is arranged as follows. In Section 2, some necessary notations, definitions, and lemmas will be introduced. In Section 3, we mainly study the exponential stability in mean square of the uncertain neutral stochastic systems with mixed delays and Markovian jumping parameters. Two illustrative numerical examples are given to show the power of our obtained results in Section 4.

Notations. Unless otherwise specified, for a real square matrix $A$, the matrix $A > 0$ ($A \geq 0$, $A < 0$, $A \leq 0$) means that $A$ is a positive definite (positive semidefinite, negative definite, and negative semidefinite, resp.); $\lambda_{\text{max}}(A)$ and $\lambda_{\text{min}}(A)$ denote the maximum and minimum eigenvalues of the square matrix $A$, respectively. Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, P)$ be a probability space with a natural $\{\mathcal{F}_t\}_{t \geq 0}$ and let $E\{\cdot\}$ stand for the mathematical expectation operator with respect to this probability measure. If $A$ is a vector or matrix, its transpose is denoted by $A^T$. $|B| = \sqrt{\text{trace}(B^T B)}$ denotes the Euclidean norm of a vector $B$ and its induced norm of a matrix $B$. Unless explicitly stated, matrices are assumed to have real entries and compatible dimensions. Let $\tau > 0$ and $C([-\tau, 0]; \mathbb{R}^n)$ be the family of all continuous $\mathbb{R}^n$-valued functions $\phi$ on the interval $[-\tau, 0]$ with the norm $\|\phi\| = \sup\{|\phi(\theta)| : -\tau \leq \theta \leq 0\}$. Denote by $L^2_0([-\tau, 0]; \mathbb{R}^n)$ the family of all $\mathcal{F}_0$-measurable $C([-\tau, 0]; \mathbb{R}^n)$-valued random variables $\xi = \{\xi(\theta) : -\tau \leq \theta \leq 0\}$ such that $\sup_{\theta \in [-\tau, 0]} E[|\xi(\theta)|^2] < +\infty$. $B(t) = [B_1(t), B_2(t), \ldots, B_n(t)]^T$ $(t \geq 0)$ is an $n$-dimensional standard Brownian motion defined on the completed probability space $(\Omega, \mathcal{F}, P)$.

2. Problem Formulation

Let $r(t)$ $(t \geq 0)$ be a right-continuous Markov chain on the probability space taking values in a finite state space $S = \{1, 2, \ldots, N\}$ with generator $\Gamma = \{\gamma_{ij}\}_{N \times N}$ given by

$$ P\{r(t + \Delta) = j \mid r(t) = i\} = \begin{cases} \gamma_{ij}\Delta + o(\Delta), & \text{if } i \neq j, \\ 1 + \gamma_{ii}\Delta + o(\Delta), & \text{if } i = j, \end{cases} \quad (2.1) $$

where $\Delta > 0$. Here, $\gamma_{ij} \geq 0$ is the transition rate from $i$ to $j$ if $i \neq j$ while

$$ \gamma_{ii} = -\sum_{j \neq i} \gamma_{ij}. \quad (2.2) $$
Now, we assume that the Markov chain $r(\cdot)$ is independent of the Brownian motion $B(\cdot)$. It is well known that almost every sample path of $r(t)$ is a right-continuous step function with a finite number of simple jumps in any finite subinterval of $R^r$.

In this paper, we will consider the following uncertain neutral stochastic systems with mixed delays and Markovian switching:

$$
\begin{align*}
\frac{d[x(t) - D(r(t))x(t - d(t))]}{dt} &= \left[ A_1(r(t), t)x(t) + A_2(r(t), t)f(x(t)) + A_3(r(t), t)f(x(t - d(t))) \right. \\
&\quad + A_4(r(t), t) \int_{t-\sigma(t)}^{t} f(x(s))ds \right] dt \\
&\quad + \sigma \left( t, x(t), x(t - d(t)), \int_{t-\sigma(t)}^{t} x(s)ds, r(t) \right) dB(t), \quad t \geq 0,
\end{align*}
$$

with the initial value $x_0 = \varphi \in L_{\mathbb{F}_0}^2([-\tau, 0], R^n)$ ($\tau = \max\{d_2, \sigma\}$), where $x(t) \in R^n$ is the system state vector associated with the neurons and $d(t)$ and $\sigma(t)$ are the time-varying delays. Here, we assume that the Markov chain $r(\cdot)$ is independent of the Brownian motion $B(t)$ ($t \geq 0$). $f : R^n \rightarrow R^n$ is neuron activation function, and the noise perturbation $\sigma : \mathbb{R}^r \times R^n \times R^n \times R^n \times \mathbb{S} \rightarrow R^{n\times n}$ is the noise intensity matrix. When $r(t) = i$ ($i \in S$), $D(r(t))$, $A_1(r(t), t)$, $A_2(r(t), t)$, $A_3(r(t), t)$, and $A_4(r(t), t)$ are, respectively, denoted as $D_i$, $A_{1i}(t)$, $A_{2i}(t)$, $A_{3i}(t)$, and $A_{4i}(t)$, and $D_i$ ($i \in S$) are known matrices with $|D_i| < 1$ ($i \in S$). $A_{1i}(t)$, $A_{2i}(t)$, $A_{3i}(t)$, and $A_{4i}(t)$ are matrix functions with time-varying uncertainties, that is,

$$
\begin{align*}
A_{1i}(t) &= A_{1i} + \Delta A_{1i}(t), \\
A_{2i}(t) &= A_{2i} + \Delta A_{2i}(t), \\
A_{3i}(t) &= A_{3i} + \Delta A_{3i}(t), \\
A_{4i}(t) &= A_{4i} + \Delta A_{4i}(t),
\end{align*}
$$

where $A_{1i}$, $A_{2i}$, $A_{3i}$, $A_{4i}$ ($i \in S$) are known real constant matrices and $\Delta A_{1i}(t)$, $\Delta A_{2i}(t)$, $\Delta A_{3i}(t)$, and $\Delta A_{4i}(t)$ ($i \in S$) are unknown matrices representing time-varying parameter uncertainties in system model. We assume that the uncertainties are norm-bounded and can be described as

$$
[\Delta A_{1i}(t) \Delta A_{2i}(t) \Delta A_{3i}(t) \Delta A_{4i}(t)] = M_iF_i(t)\begin{bmatrix} N_{1i}N_{2i}N_{3i}N_{4i} \end{bmatrix}, \quad F_i^T(t)F_i(t) \leq I, \quad i \in S,
$$

where $M_i$, $N_{1i}$, $N_{2i}$, $N_{3i}$, and $N_{4i}$ ($i \in S$) are known real matrices and $F_i(t)$ ($i \in S$) is unknown real and possibly time-varying matrix for any given $t$. It is assumed that the elements of
Discrete Dynamics in Nature and Society 5

$F_i(t) (i \in S)$ are Lebesgue measurable. When $F_i(t) = 0 (i \in S)$, systems (2.3) have the following nominal case:

$$
\begin{aligned}
&d[x(t) - D_i x(t - d(t))] = \\
&\left[ A_{1i} x(t) + A_{2i} f(x(t)) + A_{3i} f(x(t - d(t))) + A_{4i} \int_{t-\sigma_i(t)}^{t} f(x(s))ds \right] dt \\
&\quad + \sigma(t, x(t), x(t - d(t)), \int_{t-\sigma_i(t)}^{t} x(s)ds, i) dB(t), \quad t \geq 0.
\end{aligned}
$$

(2.6)

In order to obtain our results, we need some assumptions as follows.

**Assumption 2.1.** The neuron activation functions $f(\cdot)$ in (2.3) (or (2.6)) are bounded and satisfy the following Lipschitz condition:

$$
|f(x) - f(y)| \leq |L(x - y)|, \quad \forall x, y \in \mathbb{R}^n,
$$

(2.7)

where $L \in \mathbb{R}^{n \times n}$ is known constant matrix and $f(0) = 0$.

**Assumption 2.2.** The noise perturbation $\sigma$ satisfies the following condition:

$$
\text{trace} \left[ \sigma^T(\sigma(t, x(t), x(t - d(t)), \int_{t-\sigma_i(t)}^{t} x(s)ds, i)) \sigma(t, x(t), x(t - d(t)), \int_{t-\sigma_i(t)}^{t} x(s)ds, i) \right] \\
\quad \leq x^T(t) R_{1i}^T R_{1i} x(t) + x^T(t - d(t)) R_{2i}^T R_{2i} x(t - d(t)) + \left[ \int_{t-\sigma_i(t)}^{t} x(s)ds \right]^T R_{3i}^T R_{3i} \left[ \int_{t-\sigma_i(t)}^{t} x(s)ds \right],
$$

(2.8)

where $R_{1i}$, $R_{2i}$, and $R_{3i}$ are known constant matrices with appropriate dimensions and $\sigma(t, 0, 0, 0, i) = 0 (i \in S)$.

**Remark 2.3.** Under Assumptions 2.1 and 2.2, it is easily shown that the system (2.3) with uncertainties (2.4) admits a unique trivial solution when the initial data $\xi = 0$. The readers can refer to [41].

**Assumption 2.4.** $d(t)$ and $\sigma(t)$ are two time-varying continuous functions that satisfy

$$
0 \leq d_1 \leq d(t) \leq d_2, \quad \dot{d}(t) \leq \mu < 1, \quad 0 \leq \sigma(t) \leq \sigma, \quad \dot{\sigma}(t) \leq \nu < 1,
$$

(2.9)

where $d_1$ and $d_2$ are the lower and upper bounds of the time delay $d(t)$, respectively.

We present the definitions and three useful lemmas as follows.
Definition 2.5. The neutral stochastic systems with mixed delays and Markovian jump parameters (2.6) is said to be exponentially stable in mean square if there exist a pair of positive scalar \( \alpha > 0 \) and \( l > 0 \) such that every solution \( x(t, \xi, i) \) of systems (2.6) satisfies

\[
E|\xi(t, \xi, i)|^2 \leq l \sup_{s \in [-\tau, 0]} E|\varphi(s)|^2 e^{-\alpha t}, \; \forall t \geq 0, \tag{2.10}
\]

for any \( \varphi \in L^2_{b_0}([-\tau, 0], \mathbb{R}^n) \).

Definition 2.6. The uncertain neutral stochastic systems with mixed delays and Markovian jump parameters (2.3) are said to be exponentially stable in mean square if (2.10) holds for all admissible uncertainties (2.5).

Lemma 2.7 (see [8]). For any vectors \( a, b \in \mathbb{R}^n \), the inequality

\[
\pm 2a^T b \leq a^T X a + b^T X^{-1} b \tag{2.11}
\]

holds, in which \( X \) is any \( n \times n \) matrix with \( X > 0 \).

Lemma 2.8 (see [8]). Let \( X \in \mathbb{R}^{n \times n} \); then

\[
\lambda_{\min}(X) a^T b \leq a^T X b \leq \lambda_{\max}(X) a^T b \tag{2.12}
\]

for any \( a \in \mathbb{R}^n \) if \( X \) is a symmetric matrix.

Lemma 2.9 (see [42] Schur complement). For a given matrix

\[
S = \begin{pmatrix} S_{11} & S_{12} \\ S_{12}^T & S_{22} \end{pmatrix} \tag{2.13}
\]

with \( S_{11} = S_{11}^T \), \( S_{22} = S_{22}^T \), the following conditions are equivalent:

1. \( S < 0 \),
2. \( S_{22} < 0 \), \( S_{11} - S_{12} S_{22}^{-1} S_{12}^T < 0 \),
3. \( S_{11} < 0 \), \( S_{22} - S_{22}^T - S_{12} S_{12}^T S_{12} < 0 \).

Lemma 2.10 (see [42]). Let \( U, V, W \), and \( M \) be real matrices of appropriate dimensions with \( M = M^T \); then

\[
M + U V W + W^T V^T U^T < 0, \; \forall V^T V \leq I, \tag{2.14}
\]

if and only if there exist a scalar \( \varepsilon > 0 \) such that

\[
M + \varepsilon^{-1} U U^T + \varepsilon W^T W < 0. \tag{2.15}
\]
Lemma 2.11 (see [43]). For any positive symmetric constant matrix $M \in \mathbb{R}^{n \times n}$ and a scalar $\gamma > 0$, a vector function $\omega : [0, \gamma] \to \mathbb{R}^n$ such that the integrations concerned are well defined, and then the following inequality holds:

$$
\left[ \int_0^\gamma \omega(s)ds \right]^T M \left[ \int_0^\gamma \omega(s)ds \right] \leq \gamma \int_0^\gamma \omega^T(s)M\omega(s)ds.
$$

(2.16)

3. Main Results

Theorem 3.1. Suppose that Assumptions 2.1–2.4 hold and for any given positive scalar $\kappa \in (0,1)$, the neutral stochastic systems with mixed delays and Markovian switching (2.6) are exponentially stable in mean square if there exist $\lambda_i > 0$ $(i \in S)$ and some positive definite matrices $P_i > 0$ $(i \in S)$ and $Q_l > 0$ $(l = 1, 2, \ldots, 10)$ such that the following linear matrix inequalities (LMIs) are satisfied: for $i \in S$,

$$
P_i \leq \lambda_i I,
$$

(3.1)

$$
\Omega_i = \begin{bmatrix}
\Omega_{i11} & \Omega_{i12} & 0 & P_i A_{2i} & P_i A_{3i} & P_i A_{4i} & 0 & 0 & 0 \\
* & \Omega_{i22} & 0 & 0 & 0 & 0 & \Omega_{i27} & \Omega_{i28} & \Omega_{i29} \\
* & * & \Omega_{i33} & 0 & 0 & 0 & 0 & 0 & 0 \\
* & * & * & -Q_5 & 0 & 0 & 0 & 0 & 0 \\
* & * & * & * & -Q_6 & 0 & 0 & 0 & 0 \\
* & * & * & * & * & -Q_7 & 0 & 0 & 0 \\
* & * & * & * & * & * & -Q_8 & 0 & 0 \\
* & * & * & * & * & * & * & -Q_9 & 0 \\
* & * & * & * & * & * & * & * & -Q_{10}
\end{bmatrix} < 0,
$$

(3.2)

where $*$ denotes the entries that are readily inferred by symmetry of a symmetric matrix and

$$
\begin{align*}
\Omega_{i11} &= P_i A_{1i} + A^T_{1i} P_i + \sum_{j=1}^N Y_{ij} P_j + \lambda_i R_{1i}^T R_{1i} + L^T(Q_5 + Q_8)L + Q_1 + d_2 Q_2 + \frac{1}{2}(d_2^2 - d_1^2)Q_3 + \sigma^2 Q_4, \\
\Omega_{i12} &= A^T_{1i} P_i D_i - \sum_{j=1}^N Y_{ij} P_j D_i, \\
\Omega_{i22} &= L^T(Q_6 + Q_9)L + \sum_{j=1}^N Y_{ij} D^T_i P_j D_i + \lambda_i R_{2i}^T R_{2i} - (1 - \mu)Q_1, \\
\Omega_{i33} &= L^T(Q_7 + Q_{10})L + \lambda_i R_{3i}^T R_{3i} - \kappa(1 - v)Q_5, \\
\Omega_{i27} &= D^T_i P_i A_{2i}, \\
\Omega_{i28} &= D^T_i P_i A_{3i}, \\
\Omega_{i29} &= D^T_i P_i A_{4i}.
\end{align*}
$$

(3.3)
Proof. Denote by $C^{2,1} \left( R^+ \times R^n \times S; R^n \right)$ the family of all nonnegative functions $V(t, x, i)$ on $R^+ \times R^n \times S$ that are once differentiable with respect to the first variable $t$ and twice differentiable with respect to the second variable $x$. To obtain the stability conditions, we consider the following Lyapunov functional:

$$V(t, x(t), i) = V_1(t, x(t), i) + V_2(t, x(t), i) + V_3(t, x(t), i),$$

where

$$V_1(t, x(t), i) = [x(t) - D_i x(t - d(t))]^T P_i [x(t) - D_i x(t - d(t))],$$

$$V_2(t, x(t), i) = \int_{t-d(t)}^{t} x^T(s) Q_1 x(s) ds + \int_{t-d(t)}^{t} \int_s^t x^T(\theta) Q_2 x(\theta) d\theta ds,$$

$$V_3(t, x(t), i) = \int_{t-d(t)}^{t} \int_{t-s}^{t} x^T(u) Q_3 x(u) du d\theta ds + \sigma \int_{t-d(t)}^{t} \int_{t-s}^{t} x^T(\theta) Q_4 x(\theta) d\theta ds.$$

The weak infinitesimal operator $\mathcal{L}V$ [17] along (2.6) from $R^+ \times R^n \times S$ to $R$ is given by

$$\mathcal{L}V(t, x(t), i) = \mathcal{L}V_1(t, x(t), i) + \mathcal{L}V_2(t, x(t), i) + \mathcal{L}V_3(t, x(t), i),$$

where

$$\mathcal{L}V_1(t, x(t), i)$$

$$= x^T(t) \left[ P_i A_{1i} + A_{1i}^T P_i + \sum_{j=1}^{N} Y_{ij} P_j \right] x(t) + 2x^T(t) P_i A_{2i} f(x(t)) + 2x^T(t) P_i A_{3i} f(x(t - d(t))) + 2x^T(t) P_i A_{4i} \int_{t-s}^{t} f(x(s)) ds$$

$$+ 2x^T(t - d(t)) D_i^T P_i A_{1i} x(t) - 2x^T(t - d(t)) D_i^T P_i A_{2i} f(x(t)) - 2x^T(t - d(t)) D_i^T P_i A_{3i} f(x(t - d(t))) - 2x^T(t - d(t)) D_i^T P_i A_{4i} \int_{t-s}^{t} f(x(s)) ds$$

$$+ x^T(t) \left[ - \sum_{j=1}^{N} Y_{ij} P_j D_i \right] x(t - d(t)) + x^T(t - d(t)) \left[ - \sum_{j=1}^{N} Y_{ij} D_i^T P_j \right] x(t)$$

$$+ x^T(t - d(t)) \left[ \sum_{j=1}^{N} D_i^T P_j D_i \right] x(t - d(t))$$

$$+ \text{trace} \left[ \sigma^T \left( t, x(t), x(t - d(t)), \int_{t-s}^{t} x(s) ds \right) V_{1xx} \sigma \left( t, x(t), x(t - d(t)), \int_{t-s}^{t} x(s) ds \right) \right].$$

(3.7)
By Lemma 2.7, we have

\begin{equation}
    x^T(t)P_iA_{3i}f(x(t),i) \leq x^T(t)P_iA_{3i}Q_5^{-1}A_{3i}^TP_i x(t) + f^T(x(t))Q_5 f(x(t)) \\
    \leq x^T(t)P_iA_{3i}Q_6^{-1}A_{3i}^TP_i x(t) + x^T(t)L^TQ_5Lx(t),
\end{equation}

\begin{equation}
    2x^T(t)P_iA_{3i}f(x(t-d(t)),i) \leq x^T(t)P_iA_{3i}Q_6^{-1}A_{3i}^TP_i x(t) \\
    + f^T(x(t-d(t)),i)Q_6 f(x(t-d(t)),i) \\
    \leq x^T(t)P_iA_{3i}Q_6^{-1}A_{3i}^TP_i x(t) \\
    + x^T(t-d(t))L^TQ_6Lx(t-d(t)),
\end{equation}

\begin{equation}
    -2x^T(t-d(t))D^T_iP_iA_{3i}f(x(t),i) \leq x^T(t-d(t))D^T_iP_iA_{3i}Q_8^{-1}A_{3i}^TP_i D_i x(t-d(t)) \\
    + f^T(x(t))Q_8 f(x(t)) \\
    \leq x^T(t-d(t))D^T_iP_iA_{3i}Q_8^{-1}A_{3i}^TP_i D_i x(t-d(t)) \\
    + x^T(t-d(t))L^TQ_8Lx(t-d(t)),
\end{equation}

\begin{equation}
    -2x^T(t-d(t))D^T_iP_iA_{3i}f(x(t-d(t)),i) \leq x^T(t-d(t))D^T_iP_iA_{3i}Q_8^{-1}A_{3i}^TP_i D_i x(t-d(t)) \\
    + f^T(x(t-d(t)))Q_8 f(x(t-d(t))) \\
    \leq x^T(t-d(t))D^T_iP_iA_{3i}Q_8^{-1}A_{3i}^TP_i D_i x(t-d(t)) \\
    + x^T(t-d(t))L^TQ_8Lx(t-d(t)).
\end{equation}

From Lemmas 2.7 and 2.11, it implies that

\begin{equation}
    2x^T(t)P_iA_{4i} \int_{t-\sigma(t)}^t f(x(s))ds \leq x^T(t)P_iA_{4i}Q_7^{-1}A_{4i}^TP_i x(t) \\
    + \left[ \int_{t-\sigma(t)}^t f(x(s))ds \right]^TQ_7 \left[ \int_{t-\sigma(t)}^t f(x(s))ds \right] \\
    \leq x^T(t)P_iA_{4i}Q_7^{-1}A_{4i}^TP_i x(t) \\
    + \left[ \int_{t-\sigma(t)}^t x(s)ds \right]^T \left[ \int_{t-\sigma(t)}^t x(s)ds \right] L^TQ_7L \left[ \int_{t-\sigma(t)}^t x(s)ds \right],
\end{equation}

\begin{equation}
    -2x^T(t-d(t))D^T_iP_iA_{4i} \int_{t-\sigma(t)}^t f(x(s))ds \leq x^T(t-d(t))D^T_iP_iA_{4i}Q_{10}^{-1}A_{4i}^TP_i D_i x(t-d(t)) \\
    + \left[ \int_{t-\sigma(t)}^t f(x(s))ds \right]^TQ_{10} \left[ \int_{t-\sigma(t)}^t f(x(s))ds \right] \\
    \leq x^T(t-d(t))P_iA_{4i}Q_{10}^{-1}A_{4i}^TP_i x(t-d(t)) \\
    + \left[ \int_{t-\sigma(t)}^t x(s)ds \right]^T \left[ \int_{t-\sigma(t)}^t x(s)ds \right] L^TQ_{10}L \left[ \int_{t-\sigma(t)}^t x(s)ds \right].
\end{equation}
Substituting (3.8)–(3.13) into (3.7) and from Assumption 2.2, it follows that

$$
\mathcal{L}V_1(t, x(t), i) \\
\leq x^T(t) \left[ P_i A_{1i} + A_{1i}^T P_i + \sum_{j=1}^{N} Y_{ij} P_j + \lambda_i R_i^T R_i + L^T (Q_5 + Q_8) L \right. \\
+ P_i A_2 Q_5^{-1} A_2^T P_i + P_i A_3(t) Q_6^{-1} A_3^T P_i + P_i A_4 Q_7^{-1} A_4^T P_i \Bigg] x(t) \\
+ x^T(t) \left[ A_{1i}^T P_i D_i - \sum_{j=1}^{N} Y_{ij} P_i D_i \right] x(t - d(t)) + x^T(t - d(t)) \\
\times \left[ D_i^T P_i A_{1i} - \sum_{j=1}^{N} Y_{ij} D_i^T P_j \right] x(t) + x(t - d(t)) \\
\times \left[ D_i^T P_i A_2 Q_8^{-1} A_2^T P_i D_i + D_i^T P_i A_3 Q_9^{-1} A_3^T P_i D_i \right. \\
+ D_i^T P_i A_4 Q_{10}^{-1} A_4^T P_i D_i + L^T (Q_6 + Q_8) L + \sum_{j=1}^{N} Y_{ij} D_i^T P_i D_i + \lambda_i R_i^T R_i \Bigg] x(t - d(t)) \\
+ \left[ \int_{t-\sigma(t)}^{t} x(s) ds \right]^T \left[ L^T (Q_7 + Q_{10}) L + \lambda_i R_i^T R_i \right] \left[ \int_{t-\sigma(t)}^{t} x(s) ds \right] .
$$

(3.14)

On the other hand, we can obtain

$$
\mathcal{L}V_2(t, x(t), i) \leq x^T \left[ Q_1 + d_2 Q_2 \right] x(t) - (1 - \mu) x^T(t - d(t)) Q_1 x(t - d(t)) \\
- (1 - \mu) \int_{t-d(t)}^{t} x^T(s) Q_2 x(s) ds, 
$$

(3.15)

$$
\mathcal{L}V_3(t, x(t), i) \leq x^T(t) \left[ \frac{1}{2} \left( d_2^2 - d_1^2 \right) Q_3 + \sigma^2 Q_4 \right] x(t) - \int_{t-d(t)}^{t} x^T(\theta) Q_3 x(\theta) d\theta ds \\
- \sigma(1 - \nu) \int_{t-\sigma(t)}^{t} x^T(s) Q_5 x(s) ds \\
\leq x^T(t) \left[ \frac{1}{2} \left( d_2^2 - d_1^2 \right) Q_3 + \sigma^2 Q_4 \right] x(t) - \int_{t-d(t)}^{t} x^T(\theta) Q_3 x(\theta) d\theta ds \\
- \sigma(1 - \kappa)(1 - \nu) \int_{t-\sigma(t)}^{t} x^T(s) Q_5 x(s) ds \\
- \kappa(1 - \nu) \int_{t-\sigma(t)}^{t} x(s) ds \int_{t-\sigma(t)}^{t} x(s) ds .
$$

(3.16)
Substituting (3.14)–(3.16) into (3.6), we have

\[
\mathcal{L}V(t, x(t), i) \\
\leq x^T(t) \left[ P_iA_{ii} + A_{ii}^TP_i + \sum_{j=1}^{N} y_{ij}P_j + \lambda_i R_{1i}^TR_{1i} + L^T(Q_5 + Q_8)L + P_iA_{2i}Q_5^{-1} A_{2i}^TP_i \\
+ P_iA_3(t)Q_6^{-1} A_{3i}^TP_i + P_iA_4Q_7^T A_{4i}^TP_i + Q_1 + d_2Q_2 + \frac{1}{2}(d_2^2 - d_1^2)Q_3 + \sigma^2Q_4 \right] x(t) \\
+ x^T(t) \left[ A_{ii}^TP_iD_i - \sum_{j=1}^{N} y_{ij}P_jD_i \right] x(t - d(t)) + x(t - d(t)) \left[ D_{ii}^TP_iA_{ii}^T - \sum_{j=1}^{N} y_{ij}D_{ii}^TP_j \right] x(t) \\
+ x^T(t - d(t)) \left[ L^T(Q_6 + Q_8)L + D_{ii}^TP_iA_{2i}Q_6^{-1} A_{2i}^TP_iD_i + D_{ii}^TP_iA_3(t)Q_6^{-1} A_{3i}^TP_iD_i \\
+ D_{ii}^TP_iA_4Q_7^T A_{4i}^TP_iD_i + \lambda_i R_{2i}^TR_{2i} + \sum_{j=1}^{N} y_{ij}D_{ii}^TP_iD_i - (1 - \mu)Q_1 \right] x(t - d(t)) \\
+ \left[ \int_{t - d(t)}^{t} x(s)ds \right]^T \left[ L^T(Q_7 + Q_{10})L + \lambda_i R_{3i}^TR_{3i} - \kappa(1 - \nu)Q_4 \right] \left[ \int_{t - d(t)}^{t} x(s)ds \right] \\
- (1 - \mu) \int_{t - d(t)}^{t} x^T(s)Q_2x(s)ds - \int_{-d_1}^{-d_2} \int_{t + s}^{t} x^T(\theta)Q_3x(\theta)d\theta ds \\
- \sigma(1 - \kappa)(1 - \nu) \int_{t - d(t)}^{t} x^T(s)Q_5x(s)ds \\
\leq \tilde{\xi}^T(t)\Pi_i\tilde{\xi}(t) - (1 - \mu) \int_{t - d(t)}^{t} x^T(s)Q_2x(s)ds - \int_{-d_1}^{-d_2} \int_{t + s}^{t} x^T(\theta)Q_3x(\theta)d\theta ds \\
- \sigma(1 - \kappa)(1 - \nu) \int_{t - d(t)}^{t} x^T(s)Q_5x(s)ds,
\]

where \( \tilde{\xi}(t) = [x^T(t) x^T(t - d(t)) \int_{t - d(t)}^{t} x^T(s)ds]^T \) and, for \( i \in S, \)

\[
\Pi_i = \begin{bmatrix}
\Pi_{11} & \Pi_{12} & 0 \\
* & \Pi_{22} & 0 \\
* & * & \Pi_{33}
\end{bmatrix},
\]

\[
\Pi_{11} = P_iA_{ii} + A_{ii}^TP_i + \sum_{j=1}^{N} y_{ij}P_j + \lambda_i R_{1i}^TR_{1i} + L^T(Q_5 + Q_8)L + P_iA_{2i}Q_5^{-1} A_{2i}^TP_i \\
+ P_iA_3(t)Q_6^{-1} A_{3i}^TP_i + P_iA_4Q_7^T A_{4i}^TP_i + Q_1 + d_2Q_2 + \frac{1}{2}(d_2^2 - d_1^2)Q_3 + \sigma^2Q_4
\]
\[ \Pi_{12} = A_{i}^{T} P_{i} D_{i} - \sum_{j=1}^{N} P_{j} D_{j}, \]
\[ \Pi_{22} = L^{T} (Q_{0} + Q_{9}) L + D_{i}^{T} P_{i} A_{2i} Q_{8}^{-1} A_{i}^{T} P_{i} D_{i} + D_{i}^{T} P_{i} A_{3i} Q_{9}^{-1} A_{i}^{T} P_{i} D_{i} + \sum_{j=1}^{N} y_{i} D_{i}^{T} P_{j} D_{i} - (1 - \mu) Q_{1}, \]
\[ \Pi_{33} = L^{T} (Q_{7} + Q_{10}) L + \lambda_{i} \sum_{j=1}^{N} R_{j}^{T} R_{i} - \kappa (1 - \nu) Q_{4}. \]

(3.18)

In view of (3.2), we have \( \Pi_{i} < 0 \), for \( i \in S \). By the Lyapunov functional \( V(t, x(t), i) \),
\[ V(t, x(t), i) = [x(t) - D_{i} x(t - d(t))]^{T} P_{i} [x(t) - D_{i} x(t - d(t))] + \int_{t-d(t)}^{t} x^{T}(s) Q_{1} x(s) ds \]
\[ + \int_{t-d(t)}^{t} \int_{s}^{t} x^{T}(\theta) Q_{2} x(\theta) d\theta ds + \int_{t-s}^{t} \int_{\theta}^{t} x^{T}(u) Q_{3} x(u) du d\theta ds \]
\[ + \sigma \int_{-\sigma(t)}^{0} \int_{t+s}^{t} x^{T}(\theta) Q_{4} x(\theta) d\theta ds \]
\[ \leq \xi^{T}(t) \Pi_{i}^{T} \xi(t) + \int_{t-d(t)}^{t} x^{T}(s) [Q_{1} + d_{2} Q_{2}] x(s) ds + \sigma^{2} \int_{t-\sigma(t)}^{t} x^{T}(s) Q_{3} x(s) ds \]
\[ + \int_{t-\sigma(t)}^{t} x^{T}(\theta) d_{2} Q_{3} x(\theta) d\theta ds, \]

(3.19)

where
\[ \Pi_{i}' = \begin{bmatrix} P_{i} & -P_{i} D_{i} & 0 \\ -D_{i}^{T} P_{i} & D_{i}^{T} P_{i} D_{i} & 0 \\ 0 & 0 & 0 \end{bmatrix}. \]

(3.20)

Letting \( \alpha > 0 \), for system (2.6), we can define another operator \( \mathcal{L}[e^{at} V(t, x(t), i)] : \mathbb{R}^{n} \times \mathbb{R}^{n} \times S \to \mathbb{R} \) as follows:
\[ \mathcal{L}[e^{at} V(t, x(t), i)] = e^{at} [a V(t, x(t), i) + \mathcal{L} V(t, x(t), i)] \]
\[ \leq e^{at} \xi^{T}(t) [a \Pi_{i}' + \Pi_{i}] \xi(t) + \int_{t-d(t)}^{t} x^{T}(s) [a(Q_{1} + d_{2} Q_{2}) - (1 - \mu) Q_{3}] x(s) ds \]
\[ + \int_{t-s}^{t} \int_{\theta}^{t} x^{T}(\theta) [a d_{2} - 1] Q_{3} x(\theta) d\theta ds \]
\[ + \int_{t-\sigma(t)}^{t} x^{T}(s) [a \sigma^{2} - \sigma(1-\kappa)(1-\nu)] Q_{4} ds. \]

(3.21)
Now, we can choose $\alpha > 0$ sufficiently small such that
\begin{align*}
\alpha \lambda_{\max}(\Pi_i') + \lambda_{\max}(\Pi_i) &< 0, \\
\alpha(Q_1 + d_2Q_2) - (1 - \mu)Q_3 &< 0, \\
ad_2 - 1 &< 0, \\
\alpha \sigma^2 - \sigma(1 - \kappa)(1 - \nu) &< 0,
\end{align*}
for $i \in S$.

By the weak infinitesimal operator along (2.6), it is obtained from (3.21) and (3.22) that
\begin{equation}
\begin{aligned}
e^{\alpha t}EV(t, x(t), i) &\leq EV(0, x(0), i) + \int_0^t E[\mathcal{L}[e^{\alpha s}V(s, x(s), i)] ds \\
&\leq EV(0, x(0), i).
\end{aligned}
\end{equation}

Using the definition of the Lyapunov functional (3.4) again, we have
\begin{equation}
\begin{aligned}
EV(0, x(0), i) &= E[x(0) - D_1x(-d(0))]^T \Pi_1[x(0) - D_1x(-d(0))] + \int_{-d(0)}^0 E\mathcal{L} X(s)Q_1x(s) ds \\
&\quad + \int_{-d(0)}^0 \int_s^0 E\mathcal{L} X(s)Q_2x(s) ds ds + \int_{-d_2}^{d_1} \int_s^{d_2} E\mathcal{L} X(s)Q_3x(s) ds ds \\
&\quad + \sigma \int_{-\sigma(d)}^0 \int_s^0 X(s)Q_4x(s) ds ds \\
&\leq \left[2\lambda_{\max}(\Pi_1') + d_2\lambda_{\max}(Q_1) + \tau^2\lambda_{\max}(Q_2) + (d_2 - d_1)\tau^2\lambda_{\max}(Q_3) + \sigma^2\lambda_{\max}(Q_4)\right] \\
&\quad \times \sup_{\theta \in [-\sigma, 0]} E|\varphi(\theta)|^2 \\
&\triangleq M_i,
\end{aligned}
\end{equation}
for $i \in S$.

Thus, from (3.23) and (3.24), it follows that
\begin{equation}
\begin{aligned}
E|x(t) - D_1x(t - d(t))|^2 &\leq \frac{1}{\Theta} Me^{-\alpha t},
\end{aligned}
\end{equation}
where $\Theta = \min_{i \in S}\{\lambda_{\min}(\Pi_i)\}$ and $M = \max_{i \in S}\{M_i\}$. 
elementary inequality, we derive

\[ e^{et}E[x(t)|2 = e^{et}E[x(t) - D_i x(t - d(t)) + D_i x(t - d(t))]^2 \]

\[ \leq (1 + \theta)e^{et}E[x(t) - D_i x(t - d(t))]^2 + \left(1 + \frac{1}{\theta}\right)e^{et}E[D_i x(t - d(t))]^2 \]

\[ \leq \frac{1 + \theta}{\Theta}Me^{-(\alpha - \epsilon)t} + \left(1 + \frac{1}{\theta}\right)e^{et}E[D_i x(t - d(t))]^2 \]

\[ \leq \frac{1 + \theta}{\Theta}M + \bar{\epsilon}^2\left(1 + \frac{1}{\theta}\right)e^{et}E|x(t - d(t))]^2. \]  \tag{3.26}

From for all \(\epsilon \in (0, \min\{\alpha, -(2/\tau) \log |l|\})\), we have \(\bar{\epsilon}e^{et} < 1\). Thus, we can choose \(\theta\) sufficiently large such that

\[ \Delta \triangleq \bar{\epsilon}^2\left(1 + \frac{1}{\theta}\right)e^{et} < 1. \]  \tag{3.27}

So,

\[ e^{et}E[x(t)|^2 \leq \frac{1 + \theta}{\Theta}M + \Delta e^{et(t-d(t))}E[x(t - d(t))]^2. \]  \tag{3.28}

For all \(T > 0\), from (3.28), it follows that

\[ \sup_{0 \leq t \leq T}e^{et}E[x(t)|^2 \leq \frac{1 + \theta}{\Theta}M + \Delta E[\varphi]^2 + \Delta \sup_{0 \leq t \leq T}e^{et}E[x(t)|^2, \]  \tag{3.29}

that is,

\[ \sup_{0 \leq t \leq T}e^{et}E[x(t)|^2 \leq \frac{(1 + \theta)/\Theta)M + \Delta E[\varphi]^2}{1 - \Delta}. \]  \tag{3.30}

When \(T \to +\infty\), it follows from (3.30) that

\[ \sup_{0 \leq t < \infty}e^{et}E[x(t)|^2 \leq \frac{(1 + \theta)/\Theta)M + \Delta E[\varphi]^2}{1 - \Delta}. \]  \tag{3.31}

So, we can obtain

\[ E[x(t)|^2 \leq \frac{(1 + \theta)/\Theta)M + \Delta E[\varphi]^2}{1 - \Delta}e^{-et}. \]  \tag{3.32}

The proof of this theorem is completed. \(\square\)
Theorem 3.2. Suppose that Assumptions 2.1–2.4 hold and for any given positive scalar \( \kappa \in (0, 1) \), the uncertain neutral stochastic systems with mixed delays and Markovian switching (2.3) are robustly exponentially stable in mean square if there exist \( \lambda_i > 0 \) (\( i \in S \)), \( \varepsilon_{1i} > 0 \), \( \varepsilon_{2i} > 0 \) (\( i \in S \)), and some positive definite matrices \( P_i > 0 \) (\( i \in S \)) and \( Q_i > 0 \) (\( i = 1, 2, \ldots, 10 \)) such that the following linear matrix inequalities (LMIs) are satisfied:

\[
P_i < \lambda_i I, \quad i \in S, \\
\Omega_i = \begin{bmatrix}
\Omega_{11} & \Omega_{12} & 0 & \Omega_{14} & \Omega_{15} & \Omega_{16} & \Omega_{17} & \Omega_{18} & \Omega_{19} & \Omega_{110} & 0 \\
0 & \Omega_{22} & 0 & 0 & 0 & \Omega_{27} & \Omega_{28} & \Omega_{29} & 0 & \Omega_{211} \\
0 & 0 & \Omega_{33} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \Omega_{44} & \Omega_{45} & \Omega_{46} & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \Omega_{55} & \Omega_{56} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \Omega_{66} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \Omega_{77} & \Omega_{78} & \Omega_{79} & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \Omega_{88} & \Omega_{89} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \Omega_{99} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \gamma_{ij} P_j D_i & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \gamma_{ij} P_j D_i & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-\varepsilon_{1i} I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-\varepsilon_{2i} I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{bmatrix} < 0, \quad i \in S, \tag{3.33}
\]

where * denotes the entries that are readily inferred by symmetry of a symmetric matrix and

\[
\Omega_{11} = P_i A_{1i} + A_{1i}^T P_i + \sum_{j=1}^{N} \gamma_{ij} P_j + \lambda_i R_{1i}^T R_{1i} + L_i^T (Q_5 + Q_8) L + Q_1 + d_2 Q_2 + \frac{1}{2} \left( d_2^2 - d_1^2 \right) Q_3 \\
+ \sigma^2 Q_4 + (\varepsilon_{1i} + \varepsilon_{2i}) N_{i1i}^T N_{i1i}, \quad i \in S, \tag{3.34}
\]
Proof. Replacing $A_{1i}$, $A_{2i}$, $A_{3i}$, and $A_{4i}$ in (3.2) with $A_{1i} + \Delta A_{1i}(t)$, $A_{2i} + \Delta A_{2i}(t)$, $A_{3i} + \Delta A_{3i}(t)$, and $A_{4i} + \Delta A_{4i}(t)$, $\Delta A_{1i}(t)$, $\Delta A_{2i}(t)$, $\Delta A_{3i}(t)$, $\Delta A_{4i}(t)$ are described in (2.4) and (2.5), in view of Lemma 2.9 and Lemma 2.10, we obtain

$$\Pi_i(t) = \Pi_i + \Xi_i^T F_i(t) E_{1i} + E_{1i}^T F_i^T(t) \Xi_i + \Psi_i^T F_i(t) E_{2i} + E_{2i}^T F_i^T(t) \Psi_i$$

$$= \Pi_i + \varepsilon_{i1}^{-1} \Xi_i^T + \varepsilon_{i1} E_{1i} E_{1i} + \varepsilon_{i2} \Psi_i + \varepsilon_{i2} E_{2i} E_{2i}$$

$$= \Omega_i < 0,$$

where

$$\Xi_i = [M_i^T P_i ]^T, \quad \Psi_i = [0 M_i^T P_i D_i ]^T,$$

$$E_{1i} = [N_i^T 0 0 N_{2i}^T N_{3i}^T N_{4i}^T 0 0 0]^T, \quad E_{2i} = [N_i^T 0 0 0 0 N_{2i}^T N_{3i}^T N_{4i}^T ]^T,$$

where $\varepsilon_{i1} > 0$ and $\varepsilon_{i2} > 0$, for any $i \in S$. The proof of the remainder can be easily finished by following a similar line as in the proof of Theorem 3.1. The proof is completed. \hfill \Box

Remark 3.3. The delay-dependent sufficient conditions ensuring the robustly exponential stability in mean square of the uncertain neutral stochastic systems with mixed delays and Markovian switching (2.3) are provided in Theorem 3.2. It should be pointed out that such conditions are given in the form of LMIs, which could be easily solved by using the standard software packages. Besides, the criteria derived are dependent upon both the upper and lower bound of the time-varying delay and the distributed delay, which are less conservative.

Remark 3.4. Besides, by the Borel-Cantelli Lemma, we can also obtain the almost surely exponential stability of systems (2.3). Here, for the sake of brevity, we omit it and the readers can refer to [17]. Besides, we can easily come to a conclusion that the uncertain neutral stochastic delay systems with mixed delays and Markovian jumping parameters (2.3) are asymptotically stable in mean square from the conditions $|D_i| < 1$ ($i \in S$). Thus, the results given in [15] are generalized.

Case 1. Consider the problem of delay-dependent robust exponential stability for a special case of the uncertain neutral stochastic systems with mixed delays and Markovian switching in (2.6), that is,

$$d[x(t) - D_i x(t - d(t))]$$

$$= \left[ A_{1i}(t) x(t) + A_{2i}(t) f(x(t)) + A_{3i}(t) f(x(t - d(t))) + A_{4i}(t) \int_{t-\sigma(t)}^{t} f(x(s)) ds \right] dt$$

$$+ \left[ A_{5i}(t) x(t) + A_{6i}(t) x(t - d(t)) + A_{7i}(t) \int_{t-\sigma(t)}^{t} x(s) ds \right] dB(t), \quad t \geq 0,$$

(3.37)
where $A_{1i}(t), A_{2i}(t), A_{3i}(t),$ and $A_{4i}(t)$ are given in (2.3), while $A_{5i}(t), A_{6i}(t),$ and $A_{7i}(t)$ are of the following form:

$$[A_{5i}(t) \ A_{6i}(t) \ A_{7i}(t)] = [A_{5i} \ A_{6i} \ A_{7i}] + M_i F_i(t) [N_{5i} \ N_{6i} \ N_{7i}],$$

(3.38)

where $A_{5i}, A_{6i}, A_{7i}, M_i, N_{5i}, N_{6i},$ and $N_{7i} (i \in S)$ are known constant matrices. For systems (3.37), we can also obtain the robust exponential stability. The proof can be easily established by following a similar line as in the proof of Theorem 3.1 and then is omitted here.

**Theorem 3.5.** Suppose that Assumptions 2.1 and 2.2 hold and for any given positive scalar $\kappa \in (0,1)$, the uncertain neutral stochastic systems with mixed delays and Markovian switching (3.37) are robustly exponentially stable in mean square if there exist $\lambda_i > 0, \epsilon_i > 0, \epsilon_{2i} > 0, \epsilon_{3i} > 0 (i \in S)$ and some positive definite matrices $P_i > 0 (i \in S)$ and $Q_i > 0 (i = 1, 2, \ldots, 10)$ such that the following linear matrix inequalities (LMIs) are satisfied:

$$P_i \leq \lambda_i I, \ i \in S,$$

$$\begin{bmatrix}
\Gamma_{11} & \Gamma_{12} & \Gamma_{13} & \Gamma_{14} & \Gamma_{15} & \Gamma_{16} & 0 & 0 & 0 & A_{5i}^T P_i & P_i M_i & 0 & 0 \\
* & \Gamma_{22} & \Gamma_{23} & 0 & 0 & 0 & \Gamma_{27} & \Gamma_{28} & \Gamma_{29} & A_{6i}^T P_i & 0 & D_i^T P_i M_i & 0 \\
* & * & \Gamma_{33} & 0 & 0 & 0 & 0 & 0 & 0 & A_{7i}^T P_i & 0 & 0 & 0 \\
* & * & * & \Gamma_{44} & \Gamma_{45} & \Gamma_{46} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & * & * & \Gamma_{55} & \Gamma_{56} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
* & * & * & \Gamma_{66} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\

\]

(3.40)

Case 2. When \( \sigma = 0 \), the uncertain neutral stochastic systems (2.3) are described as

\[
d[x(t) - D_i x(t - d(t))] = \left[ A_{1i}(t)x(t) + A_{2i}(t)f(x(t)) + A_{3i}(t)f(x(t) - d(t)) \right]
\]

\[
+ A_{4i}(t) \int_{t-\sigma(t)}^{t} f(x(s))ds \right] dt, \quad t \geq 0.
\]

(3.41)

**Theorem 3.6.** Suppose that Assumptions 2.1 and 2.2 hold and for any given positive scalar \( \kappa \in (0, 1) \), the uncertain neutral stochastic systems with mixed delays and Markovian switching (3.41) are robustly exponentially stable in mean square if there exist \( \lambda_i > 0 \) (\( i \in S \)), \( \varepsilon_i > 0 \) (\( i \in S \)) and some positive definite matrices \( P_i > 0 \) (\( i \in S \)) and \( Q_i > 0 \) (\( i = 1, 2, \ldots, 10 \)) such that the following linear matrix inequalities (LMIs) are satisfied: for \( i \in S \),

\[
\begin{bmatrix}
    \Omega_{11} & \Omega_{12} & 0 & \Omega_{14} & \Omega_{15} & \Omega_{16} & \Omega_{17} & \Omega_{18} & \Omega_{19} & \Omega_{110} & 0 \\
    * & \Omega_{22} & 0 & 0 & 0 & 0 & \Omega_{27} & \Omega_{28} & \Omega_{29} & 0 & \Omega_{211} \\
    * & * & \Omega_{33} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
    * & * & * & \Omega_{44} & \Omega_{45} & \Omega_{46} & 0 & 0 & 0 & 0 & 0 \\

    * & * & * & * & * & \Omega_{66} & 0 & 0 & 0 & 0 & 0 \\
    * & * & * & * & * & * & \Omega_{77} & \Omega_{78} & \Omega_{79} & 0 & 0 \\
    * & * & * & * & * & * & 0 & \Omega_{88} & \Omega_{89} & 0 & 0 \\
    * & * & * & * & * & * & * & * & \Omega_{99} & 0 & 0 \\
    * & * & * & * & * & * & * & * & * & \varepsilon_{1i} I & 0 \\
    * & * & * & * & * & * & * & * & * & * & \varepsilon_{2i} I
\end{bmatrix} < 0, \quad i \in S,
\]

(3.42)
where * denotes the entries that are readily inferred by symmetry of a symmetric matrix and

\[
\Omega_{11} = P_i A_{11} + A^{T}_{11} P_i + \sum_{j=1}^{N} y_{ij} P_i + L^T(Q_5 + Q_6)L + Q_1 + d_2 Q_2 + \frac{1}{2}(d_2^2 - d_1^2)Q_3 + \sigma^2 Q_4
\]

\[+ (\varepsilon_{1i} + \varepsilon_{2i}) N_{1i}^T N_{1i}, \quad (3.43)\]

\[
\Omega_{22} = L^T(Q_5 + Q_6)L + \sum_{j=1}^{N} y_{ij} D^T_i P_i D_i - (1 - \mu)Q_1, \quad \Omega_{27} = D^T_i P_i A_{2i},
\]

\[
\Omega_{33} = L^T(Q_5 + Q_6)L - \kappa(1 - \nu)Q_4,
\]

and \(\Omega_{12}, \Omega_{14}, \Omega_{15}, \Omega_{16}, \Omega_{17}, \Omega_{18}, \Omega_{19}, \Omega_{28}, \Omega_{29}, \Omega_{33}, \Omega_{44}, \Omega_{45}, \Omega_{46}, \Omega_{53}, \Omega_{56}, \Omega_{66}, \Omega_{77}, \Omega_{78}, \Omega_{79}, \Omega_{88}, \Omega_{89}, \Omega_{99}\) are given in Theorem 3.2.

**Remark 3.7.** The sufficient conditions ensuring the exponential stability in mean square of the uncertain neutral delay systems with Markovian jumping parameters in \([39, 40]\) are dependent upon the upper bound of the exponential stability rate. But, Theorem 3.6 can remove this restrictive conditions. So, we can improve and generalize the results in \([39, 40]\).

### 4. Numerical Examples

In this section, two examples are provided to illustrate the feasibility and applicability of our obtained results.

**Example 4.1.** Consider the case of 2D Brownian motion, and \(r(t)\) is right-continuous Markovian chain taking values in \(S = \{1, 2\}\) with its generator \(\Gamma = \begin{bmatrix} 3 & -3 \\ -1 & 1 \end{bmatrix}\). And the parameters in systems (2.3) are given as follows:

\[
A_{11} = \begin{bmatrix} -1.5 & 0 \\ 0 & -1.8 \end{bmatrix}, \quad A_{12} = \begin{bmatrix} -1.8 & 0 \\ 0 & -1.8 \end{bmatrix}, \quad A_{21} = \begin{bmatrix} 0.3 & 0.2 \\ -0.6 & -0.8 \end{bmatrix}, \quad A_{22} = \begin{bmatrix} 0.6 & -0.5 \\ -0.4 & -0.3 \end{bmatrix},
\]

\[
A_{31} = \begin{bmatrix} -0.7 & -0.5 \\ 0.4 & 0.6 \end{bmatrix}, \quad A_{32} = \begin{bmatrix} 0.7 & 0.5 \\ -0.3 & 0.3 \end{bmatrix}, \quad A_{41} = \begin{bmatrix} 0.2 & 0.3 \\ -0.1 & 0.2 \end{bmatrix}, \quad A_{42} = \begin{bmatrix} 0.3 & 0.2 \\ -0.2 & 0.4 \end{bmatrix},
\]

\[
D_1 = \begin{bmatrix} -0.2 & 0.0 \\ 1.0 & 0.1 \end{bmatrix}, \quad D_2 = \begin{bmatrix} 0.1 & 0.0 \\ 0.7 & 0.2 \end{bmatrix}, \quad M_1 = \begin{bmatrix} 0.1 & 0.2 \\ 0.0 & 0.1 \end{bmatrix}, \quad M_2 = \begin{bmatrix} 0.2 & 0.1 \\ 0.1 & 0.2 \end{bmatrix},
\]

\[
N_{11} = N_{12} = N_{21} = N_{22} = N_{31} = N_{32} = N_{41} = N_{42} = \begin{bmatrix} 0.1 & 0.1 \end{bmatrix}.
\]

(4.1)

The delays \(d(t) = 0.45 \sin(t) + 0.3, \sigma(t) = 0.4 \cos(t) + 0.4\), and it is easily obtained that \(d_1 = 0.15, d_2 = 0.75, \mu = 0.45, \nu = 0.4\), and \(\sigma = 0.8\). Assume that the activation function \(f\) satisfies
Assumption 2.1 with the Lipschitz coefficient matrix $L = \begin{bmatrix} 0.2 & 0.0 \\ 0.0 & 0.2 \end{bmatrix}$ and the function $\sigma$ satisfies Assumption 2.2 with the matrices $R_{ij}$ ($i = 1, 2; j = 1, 2, 3$) given by

$$R_{11} = \begin{bmatrix} 0.15 & 0.0 \\ 0.20 & 0.35 \end{bmatrix}, \quad R_{12} = \begin{bmatrix} 0.5 & 0.1 \\ 0.28 & 0.20 \end{bmatrix}, \quad R_{21} = \begin{bmatrix} 0.3 & 0.0 \\ 0.2 & 0.1 \end{bmatrix}, \quad R_{22} = \begin{bmatrix} 0.1 & 0.0 \\ 0.2 & 0.1 \end{bmatrix}, \quad R_{31} = \begin{bmatrix} 0.1 & 0.2 \\ 0.1 & 0.2 \end{bmatrix}, \quad R_{32} = \begin{bmatrix} 0.1 & 0.1 \\ 0.2 & 0.1 \end{bmatrix}. \quad (4.2)$$

With the parameters above, when $\kappa = 0.9999$, by using Matlab LMI Toolbox, according to Theorem 3.2, we solve LMIs (3.33) and obtain there feasible solutions as follows:

$$P_1 = \begin{bmatrix} 70.0930 & 12.2285 \\ 12.2285 & 21.8248 \end{bmatrix}, \quad P_2 = \begin{bmatrix} 74.1549 & 15.4873 \\ 15.4873 & 20.7284 \end{bmatrix}, \quad Q_1 = \begin{bmatrix} 134.4662 & 25.4223 \\ 25.4223 & 20.5296 \end{bmatrix},$$

$$Q_2 = \begin{bmatrix} 1.8693 & -0.0065 \\ -0.0065 & 0.6213 \end{bmatrix}, \quad Q_3 = \begin{bmatrix} 4.8828 & -0.0153 \\ -0.0153 & 1.6598 \end{bmatrix}, \quad Q_4 = \begin{bmatrix} 16.7672 & -0.0153 \\ -0.0153 & 1.6598 \end{bmatrix},$$

$$Q_5 = \begin{bmatrix} 117.1703 & -17.8696 \\ -17.8696 & 119.1560 \end{bmatrix}, \quad Q_6 = \begin{bmatrix} 114.7061 & 67.0438 \\ 67.0438 & 91.0274 \end{bmatrix}, \quad Q_7 = \begin{bmatrix} 58.3284 & 23.0811 \\ 23.0811 & 70.1310 \end{bmatrix},$$

$$Q_8 = \begin{bmatrix} 57.0181 & 12.7280 \\ 12.7280 & 58.0073 \end{bmatrix}, \quad Q_9 = \begin{bmatrix} 41.6921 & 14.6919 \\ 14.6919 & 40.8478 \end{bmatrix}, \quad Q_{10} = \begin{bmatrix} 40.5029 & -0.2295 \\ -0.2295 & 33.2920 \end{bmatrix},$$

$$\lambda_1 = 75.3750, \quad \lambda_2 = 80.6197, \quad \varepsilon_{11} = 66.1002, \quad \varepsilon_{12} = 97.9532, \quad \varepsilon_{21} = 47.7433, \quad \varepsilon_{22} = 56.9671. \quad (4.3)$$

**Example 4.2.** Let $r(t)$ be right-continuous Markovian chain taking values in $S = \{1, 2\}$ with its generator $\Gamma = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$. Consider the following uncertain neutral systems with mixed delays and Markovian switching: for any $i \in S$,

$$\frac{d}{dt} [x(t) - D_1x(t - d(t))] = A_{1i}(t)x(t) + A_{2i}(t)x(t - d(t)), \quad t \geq 0, \quad (4.4)$$

where

$$A_{11} = A_{12} = \begin{bmatrix} -2 & 0.0 \\ 0.0 & -3 \end{bmatrix}, \quad A_{21} = A_{22} = \begin{bmatrix} -1 & 0 \\ -1 & -1 \end{bmatrix}, \quad D_1 = \begin{bmatrix} 0.3 & 0 \\ 0 & 0.3 \end{bmatrix},$$

$$D_2 = \begin{bmatrix} 0.1 & 0.0 \\ 0.0 & 0.1 \end{bmatrix}, \quad M_1 = \begin{bmatrix} 0.1 & 0.1 \\ 0.2 & 0.1 \end{bmatrix}, \quad M_2 = \begin{bmatrix} 0.2 & -0.1 \\ 0.1 & 0.1 \end{bmatrix}, \quad (4.5)$$

$$N_{11} = [0.1 \ 0.0], \quad N_{12} = [0.0 \ 0.1], \quad N_{21} = [-0.0 \ 0.1], \quad N_{22} = [0.1 \ 0.1].$$
Applying Matlab toolbox, by Theorem 3.6, for $\mu = 0$, it can be obtained that the uncertain neutral systems with delays and Markovian jumping parameters (4.4) are robustly exponentially stable in mean square with the delay $d(t)$ satisfying $0 \leq d(t) \leq 6.0 \times 10^{17}$.

5. Conclusions

In this paper, the exponential stability in mean square of the uncertain neutral stochastic systems with mixed delays and Markovian jumping parameters has been considered. The mixed delays consist of the discrete delay and the distributed delay. The LMI-based conditions ensuring the exponential stability in mean square of such systems are obtained by constructing an appropriate Lyapunov functional, which are dependent upon the upper bound and lower bound of the discrete time delays and distributed delays. It is worth pointing out that, compared with the previous works [17, 18], the stability criteria in this paper can be easily checked by using some standard numerical packages. Two illustrative examples are provided to show the effectiveness and applicability of the proposed results.
