We establish a general existence result for Galerkin’s approximate solutions of abstract semilinear equations and conduct an error analysis. Our results may be regarded as some extension of a precedent work (Schultz 1969). The derivation of our results is, however, different from the discussion in his paper and is essentially based on the convergence theorem of Newton’s method and some techniques for deriving it. Some of our results may be applicable for investigating the quality of numerical verification methods for solutions of ordinary and partial differential equations.

1. Introduction

Let $X$ be a real Hilbert space and $X_h \subset X$ be a closed subspace. Here, $h$ is a positive parameter (which will tend to zero). We denote by $P_h$ the orthogonal projection onto $X_h$. We assume that

$$\lim_{h \to 0} \| (I - P_h)u \| = 0 \quad \text{for any } u \in X,$$

where $I : X \to X$ is the identity operator. We are interested in studying error analysis of Galerkin’s method for the following equation:

$$f(u) := u - \varphi(u) = 0.$$  (1.1)
Here, \( \varphi : U \to X \) is a nonlinear map and \( U \) is a subset of \( X \). We define \( \tilde{f}_h : U \cap X_h \to X_h \) by
\[
\tilde{f}_h(u) := P_h f(u) \quad \text{for } u \in U \cap X_h. \tag{1.2}
\]

The equation \( \tilde{f}_h(u) = 0 \) is the Galerkin approximate equation of (1.1). A precedent work [1] by Schultz reads as follows.

**Theorem 1.1** (see [1, Theorems 3.1 and 3.2]). One assumes (H1). Let \( R \in (0, \infty) \) be a constant and \( U = \{ u \in X; \|u\| \leq R \} \). One assumes that \( \varphi : U \to X \) is a completely continuous map such that \( \varphi(U) \subset U \). Then the following holds.

(i) The equation \( \tilde{f}_h(u) = 0 \) has a solution \( u_h \) in \( U \cap X_h \) for any \( h \) and there exists a monotone decreasing sequence \( \{ h_k \}_{k=1}^{\infty} \) with \( \lim_{k \to \infty} h_k = 0 \) and \( u_{k} \in U \) such that \( u_{h_k} \to u_{\infty} \) in \( X \) as \( k \to \infty \) and \( u_{\infty} \) is a solution of (1.1). Moreover, if \( u_{\infty} \) is the unique solution of (1.1) in \( U \), then one has \( \lim_{h \to 0} u_h = u_{\infty} \) in \( X \).

(ii) Let \( u_* \in U \) be a solution of (1.1). If \( \varphi \) has a Fréchet derivative, in a neighborhood, \( \mathcal{N} \), of \( u_* \) and 0 is not in the spectrum of \( f' \), then \( u_* \) is the unique solution of (1.1) in \( \mathcal{N} \) and \( \tilde{f}_h(u) = 0 \) has a solution \( u_h \in X_h \) for any \( h \), which is unique for sufficiently small \( h \) and
\[
\|u_* - u_h\| \approx \|(I - P_h)u_*\|, \tag{1.3}
\]
which means that \( \|u_* - u_h\| \) and \( \|(I - P_h)u_*\| \) are equivalent infinitesimals as \( h \to 0 \).

In this paper, we always assume (H1) and the following (H2) in what follows:
\[
\varphi \in C^1(U, X), \quad \text{and } \varphi'(u) \in L(X) \quad \text{is compact for any } u \in U, \tag{H2}
\]
where \( U \subset X \) is an open set. Under the conditions (H1) and (H2), we obtain results similar to Theorem 1.1 (see Proposition 2.1 and Corollary 2.3). We also establish new other results on error analysis (see Theorems 2.4 and 2.5). Our results may be regarded as some extension of Theorem 1.1. The derivation of our results is, however, different from the proof of Theorem 1.1, which is based on the Brower fixed point theorem and the equality (4.10). Our proofs are essentially based on the convergence theorem of Newton’s method (Theorem 3.2) and some techniques for deriving it. We remark that a version of the same theorem is applied in [2] to an ordinary periodic system for a purpose similar to ours.

Various ordinary and partial differential equations appearing in mathematical physics can be written in the form (1.1) with (H2) under an appropriate setting of the functional spaces. See Section 5 for some concrete examples.

We define \( f_h : U \to X \) by
\[
f_h(u) := u - P_h \varphi(u) \quad \text{for } u \in U. \tag{1.4}
\]

The map \( f_h \) is a natural extension of \( \tilde{f}_h \) and is very useful in our analysis below. Obviously, \( u \) is a solution of \( \tilde{f}_h(u) = 0 \) if and only if \( u \) is a solution of \( f_h(u) = 0 \). We can treat the equation \( f_h(u) = 0 \) more easily than \( \tilde{f}_h(u) = 0 \) since \( f_h \) is defined globally.
One of our motivations for this study is to investigate the quality of a numerical verification method for solutions of differential equations. Some of our results in this paper may be applicable for such a purpose. See Remark 2.7 for further information.

The paper is organized as follows. In Section 2 we describe our main results. We prepare some preliminary abstract results in Section 3 and apply them to prove our main results in Section 4. In Section 5 we present some concrete examples on semilinear elliptic partial differential equations.

**Notations.** Let \( \mathcal{X} \) and \( \mathcal{Y} \) be Banach spaces.

1. We denote by \( \| \cdot \|_{\mathcal{X}} \) the norm of \( \mathcal{X} \). If \( \mathcal{X} \) is a Hilbert space, then \( \| \cdot \| \) stands for the norm induced by the inner product of \( \mathcal{X} \). For \( u \in \mathcal{X} \) and \( r \in (0, \infty) \), we write \( B_{\mathcal{X}}(u; r) := \{ v \in \mathcal{X}; \| v - u \| < r \} \). The subscript will be often omitted if no possible confusion arises.

2. For an open set \( V \subset \mathcal{X} \), \( C^1(V, \mathcal{Y}) \) denotes the space of continuously differentiable functions from \( V \) to \( \mathcal{Y} \).

3. We denote by \( \mathcal{L}(\mathcal{X}, \mathcal{Y}) \) the space of bounded linear operators from \( \mathcal{X} \) to \( \mathcal{Y} \) and \( \mathcal{L}(\mathcal{X}) \) stands for \( \mathcal{L}(\mathcal{X}, \mathcal{X}) \). For \( T \in \mathcal{L}(\mathcal{X}, \mathcal{Y}) \), \( \| T \|_{\mathcal{X} \rightarrow \mathcal{Y}} \) denotes the operator norm of \( T \). The subscript will be omitted if no possible confusion arises.

4. Let \( \phi(h) \) and \( \psi(h) \) be nonnegative functions. We write \( \phi(h) \sim \psi(h) \) if \( \phi(h) \) and \( \psi(h) \) are infinitesimals of the same order as \( h \to 0 \), that is, \( \phi(h) = O(1) \psi(h) \) as \( h \to 0 \). We write \( \phi(h) \asymp \psi(h) \) if \( \phi(h) \) and \( \psi(h) \) are equivalent infinitesimals as \( h \to 0 \), that is, \( \phi(h) = \{1 + o(1)\} \psi(h) \) as \( h \to 0 \).

5. Let \( \Omega \) be a bounded domain of \( \mathbb{R}^n \). We denote Lebesgue spaces by \( L^p(\Omega)(1 \leq p \leq \infty) \) with the norms \( \| u \|_{L^p(\Omega)} = \left( \int_{\Omega} |u(x)|^p \, dx \right)^{1/p} \) for \( 1 \leq p < \infty \), \( \| u \|_{L^\infty(\Omega)} = \text{ess. sup} \{ |u(x)|; x \in \Omega \} \). We denote by \( H^1_0(\Omega) \) the completion of \( C_c^\infty(\Omega) \) (the space of \( C^\infty \) functions with compact support in \( \Omega \)) in the Sobolev norm: \( \| u \| = \| \nabla u \|_{L^2(\Omega)} := \left( \sum_{k=1}^n \| \partial u / \partial x_k \|_{L^2(\Omega)}^2 \right)^{1/2} \). We denote by \( H^{-1}(\Omega) \) the Sobolev space \( \{ F \in \mathfrak{S}'(\Omega); \exists C \in (0, \infty) \text{ such that } |F(\phi)| \leq C \| \phi \|_{H^{-1}(\Omega)} \text{ for any } \phi \in C^\infty_c(\Omega) \} \) with the norm \( \| F \|_{H^{-1}(\Omega)} = \text{sup} \{ |F(\phi)|; \phi \in C^\infty_c(\Omega) \text{ and } \| \phi \|_{H^{-1}(\Omega)} \leq 1 \} \). Here, \( \mathfrak{S}'(\Omega) \) stands for the set of distributions on \( \Omega \).

**2. Main Results**

In this section we describe our main results. We assume (H1) and (H2). Let \( u_* \in U \) be an isolated solution of (1.1), that is, \( u_* \) is a solution of (1.1) such that \( f'(u_*) : X \to X \) is bijective. We set

\[
T := \psi'(u_*), \quad A := I - T = f'(u_*), \quad A_h := I - P_h TP_h, \tag{2.1}
\]

for simplicity. The operator \( A_h \) is an almost diagonal operator introduced in [3]. First we have an existence theorem for Galerkin’s approximate solutions of (1.1).

**Proposition 2.1.** There exist \( h_* > 0 \) and \( \{ u_h \}_{h \in (0,h_*)} \subset U \) such that the following (i)–(iii) hold.

(i) There exists \( R_* > 0 \) such that \( u = u_h \) is the only solution of \( f_h(u) = 0 \) in \( B(u_*, R_*) \) for any \( h \in (0, h_*) \).
(ii) \( u = u_h \) is an isolated solution of \( f_h(u) = 0 \) for any \( h \in (0, h_*) \).

(iii) \( u_h \to u_* \) in \( X \) as \( h \to 0 \) with the estimate

\[
\|u_* - u_h\| \leq C_h \|f_h(u_*)\| = C_h \|(I - P_h)u_*\| \quad \text{for any} \quad h \in (0, h_*), \tag{2.2}
\]

where \( \{C_h\}_{h \in (0, h_*)} \subset (1, 2) \) and \( C_h \to 1 \) as \( h \to 0 \).

**Remark 2.2.** (i) Proposition 2.1(ii) is useful in our analysis below. Moreover, we immediately obtain from it that \( u = u_h \) is an isolated solution of \( f_h(u) = 0 \) for any \( h \in (0, h_*) \). This guarantees that we can always construct a Galerkin approximate solution \( u_h \) by Newton’s method for small \( h > 0 \).

(ii) In various contexts in applications, \( X_h \) is finite-dimensional for any \( h \). In such contexts the assumption (H1) implies that \( X \) is separable.

(iii) We do not assume \( \dim X_h < \infty \). We briefly explain that it has some practical benefits. The case \( \dim X_h = \infty \) appears, for example, in the following context. We are interested in the semi-discrete approximation to a periodic system described by a partial differential equation with a periodic forcing term. We may apply a Galerkin method only in space to the original system in order to construct a simpler approximate system described by ordinary differential equations. Then, for an isolated periodic solution of the original system, our Proposition 2.1 may guarantee that in a small neighborhood of it the approximate system has a periodic solution. For example, we can actually apply Proposition 2.1 to a semi-discrete approximation to a periodic system treated in [3]. See [4, Remark 3.4] for how to rewrite the system in [3] as (1.1).

In what follows in this section, \( \{u_h\}_{h \in (0, h_*)} \) always denotes the sequence as described in Proposition 2.1. Since \( u_* - u_h \) is decomposed into the \( X_h \)-component \( P_h u_* - u_h \) and the \( X_{h^*} \)-component \( (I - P_h)u_* \), we have \( \|u_* - u_h\|^2 = \|P_h u_* - u_h\|^2 + \|(I - P_h)u_*\|^2 \) and \( \|(I - P_h)u_*\| \leq \|u_* - u_h\| \). So, the last inequality and (2.2) immediately imply (2.3) below.

**Corollary 2.3.** We have

\[
\|u_* - u_h\| = \|f_h(u_*)\| = \|(I - P_h)u_*\|, \tag{2.3}
\]
\[
\|P_h u_* - u_h\| = o(\|(I - P_h)u_*\|) \quad \text{as} \quad h \to 0, \tag{2.4}
\]
\[
\|P_h u_* - u_h\| = o(\|u_* - u_h\|) \quad \text{as} \quad h \to 0. \tag{2.5}
\]

Actually, we easily verify that (2.3), (2.4) and (2.5) are mutually equivalent. They are very general features for the Galerkin method. The estimate (2.5) means that the \( X_{h^*} \)-component of the error \( \|P_h u_* - u_h\| \) is an infinitesimal of a higher order of smallness with respect to the whole error \( \|u_* - u_h\| \) as \( h \to 0 \).

The following two results are useful for applications (see Remark 2.7 below).
Theorem 2.4. We have the following:

\[ \|u_s - u_h\| \simeq \|f(u_h)\| = \|(I - P_h)\varphi(u_h)\| \simeq \|A^{-1}f(u_h)\|, \]
\[ \|P_h u_s - u_h\| \simeq \|A^{-1}f_h(P_h u_s)\| \simeq \|P_h A_h^{-1}f(P_h u_s) - \|P_h (\varphi(u_s) - \varphi(P_h u_s))\|. \]

(2.6)

(2.7)

Theorem 2.5. (i) We have

\[ \sup_{s \in [0,1]} \|\varphi'((1 - s)u_s + sP_h u_s)(I - P_h)\| \longrightarrow 0 \quad \text{as} \quad h \longrightarrow 0. \]

(2.8)

(ii) Let \( \varepsilon_h \) be a positive constant for \( h \in (0, h_s) \) such that

\[ \varepsilon_h \geq \sup_{s \in [0,1]} \|\varphi'((1 - s)u_s + sP_h u_s)(I - P_h)\| \]

for any \( h \in (0, h_s) \). Then, there exist constants \( h_1 \in (0, h_s) \) and \( C_1 \) such that

\[ \|P_h u_s - u_h\| \leq C_1 \varepsilon_h \|(I - P_h)u_s\| \quad \text{for any} \quad h \in (0, h_1). \]

(2.10)

In view of Theorem 2.5 (i) and (ii), we can always take \( \{\varepsilon_h\}_{h \in (0, h_s)} \) in (2.10) such that \( \varepsilon_h \to 0 \) as \( h \to 0 \). The following Remarks 2.6 and 5.3 below shows that our estimate (2.10) is in general sharper than an estimate which can be derived directly from the discussion in [1].

Remark 2.6. (i) In the same way as in the proof of [1, Theorem 3.2] we can obtain an estimate related to (2.10). We set \( \eta_h := (2p_h + q_h + r_h)/(1 - (p_h + q_h + r_h)) \), \( p_h := \|A^{-1}(I - P_h)T\| \), \( q_h := \|A^{-1}P_hT(I - P_h)\| \) and \( r_h := \|A^{-1}\| \cdot \|\varphi(u_h) - \varphi(u_s) - T(u_h - u_s)\| / \|u_h - u_s\| \). It follows from Proposition 2.1 (iii) and Proposition 3.1 below that \( p_h, q_h \) and \( r_h \) converge to 0 as \( h \to 0 \). So, \( \eta_h \to 0 \) as \( h \to 0 \). Let \( \tilde{\varepsilon}_h \) be a positive constant for \( h \in (0, h_s) \) such that \( \tilde{\varepsilon}_h \geq \sqrt{\eta_h^2 + 2\eta_h} \). Then we have

\[ \|P_h u_s - u_h\| \leq \tilde{\varepsilon}_h \|(I - P_h)u_s\| \quad \text{for any} \quad h \in (0, h_1). \]

(2.11)

We can verify that

\[ \tilde{\varepsilon}_h \text{ is larger than } \|(I - P_h)T\|^{1/2} \text{ for sufficiently small } h > 0. \]

(2.12)

Indeed, we immediately obtain (2.12) from

\[ p_h \approx \|(I - P_h)T\|. \]

(2.13)

We derive (2.11) and (2.13) at the end of Section 4.

(ii) When we compute \( \tilde{\varepsilon}_h \) for concrete examples (e.g., examples in Section 5 below), it seems reasonable to estimate \( q_h \) as \( q_h \leq C \|T(I - P_h)\| \). Here, \( C \) represents some positive
constant independent of $h$. Then, it is actually necessary to take $\hat{\varepsilon}_h$ such that $\hat{\varepsilon}_h \geq C\|T(I - P_h)\|^{1/2}$ for small $h > 0$. On the other hand, roughly speaking, (2.9) means that we can take $\varepsilon_h \simeq \|T(I - P_h)\|$ for small $h > 0$ (See Remark 5.3 below). (We note that Proposition 3.1 below implies that $\|T(I - P_h)\| \to 0$ as $h \to 0$.)

(iii) We consider the case where $T$ is self-adjoint (e.g., Example 5.1 below). In this case, we have $\|(I - P_h)T\| = \|T(I - P_h)\|$. So, by (2.12) $\hat{\varepsilon}_h$ is larger than $\|T(I - P_h)\|^{1/2}$ for small $h > 0$.

Remark 2.7. We mention applications of our results. Some of our results may be applicable for testing the quality of a numerical verification algorithm for solutions of differential equations. In general we obtain an upper bound of $\|u_n - u_h\|$ as output data from a numerical verification algorithm (See e.g., [5] and the references therein). By our Theorem 2.4 $\|u_n - u_h\|$ is sufficiently close to $\|f(u_h)\|$ for sufficiently small $h$. So, Theorem 2.4 shows that we can check the accuracy of the output upper bound of $\|u_n - u_h\|$ by finding the value of $\|f(u_h)\|$ when $h$ is small. In [5] we proposed a numerical verification algorithm which also gives upper bounds of $\|P_hu_n - u_h\|$ as output data. Our Theorem 2.5 may be applicable for testing the accuracy of such upper bounds. See Remark 5.4 for more detailed information.

3. Preliminary Abstract Results

In this section, we prepare some abstract results in order to prove our main results in Section 2.

Proposition 3.1. We assume (H1). Let $K : X \to X$ be a compact operator. Then we have the following:

\[
P_hK \to K, \quad KP_h \to K \quad \text{in } \mathcal{L}(X) \text{ as } h \to 0, \tag{3.1}
\]

\[
P_hKP_h \to K \quad \text{in } \mathcal{L}(X) \text{ as } h \to 0. \tag{3.2}
\]

Proof. Though this result was proved in [6, Section 78], we give a simpler proof for the convenience of the reader. First we show that

\[
\|K(I - P_h)\| \to 0 \quad \text{as } h \to 0. \tag{3.3}
\]

We proceed by contradiction. We assume that (3.3) does not hold. Then we have $\delta := \limsup_{h \to 0} \|K(I - P_h)\| > 0$. Therefore, there exist $\{h_n\}_{n=1}^{\infty}$ and $\{u_n\}_{n=1}^{\infty} \subset X$ such that $h_n \searrow 0$ as $n \to \infty$, $\|u_n\| = 1$ for $n \in \mathbb{N}$ and

\[
\|K(I - P_{h_n})u_n\| \geq \frac{\delta}{2} \quad \text{for any } n \in \mathbb{N}. \tag{3.4}
\]

Since $K$ is compact and $(I - P_{h_n})u_n$ converges weakly to 0, we have $\|K(I - P_{h_n})u_n\| \to 0$ as $n \to \infty$. This contradicts (3.4). So, (3.3) holds. Since $K^*$ is also compact, we obtain

\[
\|(I - P_h)K\| = \|\{(I - P_h)K\}^*\| = \|K^*(I - P_h)\| \to 0 \quad \text{as } n \to \infty. \tag{3.5}
\]

So, we have (3.1), which implies (3.2). □
Next, we describe some results in a more general setting. In what follows in this section, let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces and $U \subset \mathcal{X}$ be an open set. We assume $F \in C^1(U, \mathcal{Y})$.

**Theorem 3.2.** Let $u_0 \in U$ and $L \in \mathcal{L}(\mathcal{X}, \mathcal{Y})$ be bijective. We define a map $g : U \rightarrow \mathcal{X}$ by

$$g(u) := u - L^{-1}F(u).$$

(3.6)

Let $R > 0$ be a constant satisfying $\overline{B(u_0; R)} \subset U$ and $b : [0, R] \rightarrow [0, \infty)$ be a non-decreasing function such that

$$\sup\{\|g'(u)\| : u \in \overline{B(u_0; r)}\} \leq b(r) \quad \text{for any } r \in [0, R].$$

(3.7)

Let $\varepsilon_0 \geq 0$ be a constant such that

$$\left\|L^{-1}F(u_0)\right\| \leq \varepsilon_0.$$  

(3.8)

We assume that there exist constants $r_0$ and $r_1$ such that $0 < r_0 \leq r_1 \leq R$,

$$\varepsilon_0 + \int_0^{r_0} b(r)dr \leq r_0,$$

(3.9)

$$b(r_1) < 1.$$  

(3.10)

Then the equation $F(u) = 0$ has an isolated solution $u_* \in \overline{B(u_0; r_0)}$. Moreover, the solution of $F(u) = 0$ is unique in $\overline{B(u_0; r_1)}$.

**Remark 3.3.** (i) Theorem 3.2 is a new version of the convergence theorem of simplified Newton’s method, which is a refinement of the classical versions such as [5, Theorem 0.1]. Actually, the former implies the latter.

(ii) The convergence theorem of simplified Newton’s method is a very strong and general principle to verify the existence of isolated solutions. The reason is, roughly speaking, that the condition of the theorem is not only a sufficient condition to guarantee an isolated solution but also virtually a necessary condition for an isolated solution to exist. See [4, Remark 1.3] for the detail.

**Proof of Theorem 3.2.** Though we may consider Theorem 3.2 as a corollary of [5, Theorem 1.1], we describe the proof for completeness. We easily verify that $u$ is a solution of $F(u) = 0$ if and only if $u$ is a fixed point of $g(u)$. Let $u, v \in U$. We obtain

$$g(u) - g(v) = \int_0^1 \frac{d}{dt}g(v + t(u - v))dt = \int_0^1 g'(v + t(u - v))dt(u - v).$$

(3.11)

By (3.7) and (3.11) we have

$$\|g(u) - g(v)\| \leq b(r)\|u - v\| \quad \text{for any } r \in (0, R] \text{ and } u, v \in \overline{B(u_0; r)}.$$  

(3.12)
We set \( B_0 := \overline{B(u_0; r_0)} \). Let \( u \in B_0 \). In view of (3.7), (3.8), and (3.11) with \( v := u_0 \), we have

\[
\|g(u_0) - u_0\| = \left\| L^{-1} F(u_0) \right\| \leq \varepsilon_0, \tag{3.13}
\]

\[
\|g(u) - g(u_0)\| \leq r_0 \int_0^1 b(r_0 t) dt = \int_0^{r_0} b(r) dr. \tag{3.14}
\]

Combining (3.9), (3.13), and (3.14), we have \( \|g(u) - u_0\| \leq r_0 \), which implies \( g(B_0) \subset B_0 \). Therefore, in view of (3.10) and (3.12) \( g \) is a contraction on \( B_0 \). By the contraction mapping principle there exists a unique solution \( u = u_* \) on \( B_0 \) for the equation \( F(u) = 0 \). We immediately obtain from (3.10) and (3.12) that the solution of \( F(u) = 0 \) is unique on \( \overline{B(u_0; r_1)} \). Finally, it suffices to show that

\[
F'(u) : \mathcal{X} \rightarrow \mathcal{Y} \text{ is bijective for any } u \in \overline{B(u_0; r_1)} \tag{3.15}
\]

in order to prove that \( u_* \) is isolated. We denote by \( I \) the identity operator on \( \mathcal{X} \). Let \( u \in B(u_0; r_1) \). Then, by (3.7) and (3.10) we have \( \|g'(u)\| \leq b(r_1) < 1 \). This implies that \( I - g'(u) : \mathcal{X} \rightarrow \mathcal{X} \) is bijective. Since \( L \) is also bijective and \( F'(u) = L(I - g'(u)) \), (3.15) holds.

The next result may be considered as a refinement of [7, Theorem 3.1 (14)] and [8, Theorem 3.1 (23)].

**Proposition 3.4.** Let \( u, v \in U, (1 - s)u + sv \in U \) for any \( s \in (0, 1) \) and \( L \in \mathcal{L}(\mathcal{X}, \mathcal{Y}) \) be bijective. We set \( m := \max_{s \in [0, 1]} \|L - F'((1 - s)u + sv)\| \). Then we have

\[
\frac{\left\| L^{-1}(F(u) - F(v)) \right\|}{1 + m\left\| L^{-1} \right\|} \leq \|u - v\|. \tag{3.16}
\]

Moreover, if \( m\|L^{-1}\| < 1 \) then we also obtain

\[
\|u - v\| \leq \frac{\left\| L^{-1}(F(u) - F(v)) \right\|}{1 - m\|L^{-1}\|}. \tag{3.17}
\]

**Proof.** The proof is similar to that of Theorem 3.2. Let \( g : U \rightarrow \mathcal{X} \) be a map defined by (3.6). We have

\[
u - v = g(u) - g(v) + L^{-1}(F(u) - F(v)). \tag{3.18}\]

It follows from (3.11) that \( \|g(u) - g(v)\| \leq m\|L^{-1}\|\|u - v\| \). Combining this inequality and (3.18), we obtain (3.16) and (3.17). \( \square \)
Theorem 3.5. Let \( u = u_* \in U \) be an isolated solution of the equation \( F(u) = 0 \). Let \( h_0 > 0 \) be a positive constant, \( F_h \in C^1(U, \mathcal{Y}) \) and \( H_h \in \mathcal{L}(\mathcal{X}, \mathcal{Y})(0 < h < h_0) \). We set \( H := F'(u_*) \). We assume that

\[
F_h(u_*) \to 0 \quad \text{in} \ \mathcal{Y} \quad \text{as} \ h \to 0, \tag{3.19}
\]

\[
F_h'(u_*) \to H_h \quad \text{in} \ \mathcal{L}(\mathcal{X}, \mathcal{Y}) \quad \text{as} \ h \to 0, \tag{3.20}
\]

\[
\lim_{r \searrow 0} d(r, u) = 0 \quad \text{for any} \ u \in U. \tag{3.21}
\]

Here, \( d(r, u) := \sup \{ \| F_h'(u) - F_h'(v) \| : 0 < h < h_0 \text{ and } v \in U \cap \overline{B(u; r)} \} \). Then, there exist a constant \( h_* \in (0, h_0) \) and sequences \( \{ c_h \}_{h \in (0, h_0)} \subset (1, 2), \{ u_h \}_{h \in (0, h_0)} \subset U \) such that the following (a)-(f) hold:

(a) \[
c_h \to 1 \quad \text{as} \ h \to 0, \tag{3.22}
\]

(b) \( u = u_h \) is an isolated solution of \( F_h(u) = 0 \) for any \( h \in (0, h_*) \),

(c) \[
\| u_h - u_* \|_\mathcal{X} \leq c_h \| H_h^{-1} F_h(u_*) \|_\mathcal{X} \quad \text{for any} \ h \in (0, h_*), \tag{3.23}
\]

(d) \( H_h \) is bijective with \( \| H_h - F_h'(u_*) \| < 1/2 \| H_h^{-1} \| \) and \( \| H_h^{-1} \| < 2 \| H^{-1} \| \) for any \( h \in (0, h_*) \),

(e) the solution of \( F_h(u) = 0 \) is unique in \( B(u_*; R_h) \) for any \( h \in (0, h_*) \), where

\[
R_h := \sup \left\{ R > 0; B(u_*; R) \subset U, d(R, u_*) < \frac{1}{\| H_h^{-1} \|} - \| H_h - F_h'(u_*) \| \right\} > 0, \tag{3.24}
\]

(f) \[
c_h \| H_h^{-1} F_h(u_*) \| < R_h \quad \text{for any} \ h \in (0, h_*). \tag{3.25}
\]

Proof. By (3.20) and the stability property of linear operators (e.g., [3, Corollary 2.4.1]), \( F_h'(u_*) \) and \( H_h \) are bijective for sufficiently small \( h > 0 \) and \( F_h'(u_*)^{-1} \to H^{-1}, H_h^{-1} \to H^{-1} \) in \( \mathcal{L}(\mathcal{Y}, \mathcal{X}) \) as \( h \to 0 \). Let \( \eta_h := \| H_h^{-1} F_h(u_*) \| \) and \( g_h(u) := u - H_h^{-1} F_h(u) \). We set \( d(r) := d(r, u_*) \) for \( r > 0 \) and define \( b_h(r) := \| H_h^{-1} \| \{ \| H_h - F_h'(u_*) \| + d(r) \} \). Let \( c_h := 1/(1 - b_h(2\eta_h)), r_h := c_h \eta_h \) and \( \delta_h := (1/2 \| H_h^{-1} \|) - \| H_h - F_h'(u_*) \| \). Then, we easily verify that as \( h \to 0 \),

\[
\eta_h \to 0, \quad c_h \to 1, \quad r_h \to 0, \quad \delta_h \to \frac{1}{2 \| H^{-1} \|} (> 0). \tag{3.26}
\]
Therefore, there exist \( h_\ast \in (0, h_0) \) and \( \varepsilon \in (0, 1) \) such that for any \( h \in (0, h_\ast) \), \( F'_h(u_\ast) \) is bijective with (d), \( 1 \leq c_h < 2, d(r_h + \varepsilon) < \delta_h \) and \( \overline{B(u_\ast; r_h + \varepsilon)} \subset U \). It follows that \( \|g'_h(u)\| \leq b_h(r) \) for any \( h \in (0, h_\ast) \), \( r > 0 \), and \( u \in U \cap \overline{B(u_\ast; r)} \). We also have \( r_h + \varepsilon \leq R_h \) and

\[
\eta_h + \int_0^{r_h} b_h(r) \, dr \leq \eta_h + r_h b_h(r_h) \leq r_h.
\]

(3.27)

Let \( h \in (0, h_\ast) \) and \( R \in (r_h, R_\ast) \). We apply Theorem 3.2 by setting \( F := F_h, u_0 := u_\ast, L := H_h, b := b_h, r_0 := r_h, r_1 := R \) and \( \varepsilon_0 := \eta_h \). Then, we obtain the desired conclusions.

Remark 3.6. Theorem 3.5 is related to [7, Theorem 3.1] and [8, Theorem 3.1]. Actually, their proofs are similar to ours. Our proof is based on the convergence theorem of simplified Newton’s method, from which they may be derived similarly.

4. Proofs of Main Theorems

We prove the results in Section 2. We use the notation (2.1).

Proof of Proposition 2.1. We apply Theorem 3.5 by putting \( X = Y := X, F := f, F_h := f_h, H := A \) and \( H_h := A_h \). We show (3.19)–(3.21). By (H1) we have \( f_h(u_\ast) = (I - P_h)u_\ast \to 0 \) in \( X \) as \( h \to 0 \). Therefore, (3.19) holds. It follows from (H2) and Proposition 3.1 that

\[
f'_h(u_\ast) = I - P_h T \to I - T = A, \quad A_h \to A \quad \text{in} \quad \mathcal{L}(X) \quad \text{as} \quad h \to 0.
\]

(4.1)

So, (3.20) holds. Let \( r > 0, u \in U \) and \( v \in U \cap \overline{B(u_\ast; r)} \). Since \( \varphi' \) is continuous, we have \( \|f'_h(u) - f'_h(v)\| \leq \|\varphi'(u) - \varphi'(v)\| \to 0 \) as \( r \searrow 0 \), which implies (3.21). Therefore, by Theorem 3.5, there exist a small constant \( h_0 > 0 \), \( \{u_h\}_{h \in (0, h_0)} \) and \( \{C_k\}_{h \in (0, h_0)} \) such that (a)–(f) with \( c_h := C_h \) hold. So, we immediately obtain (ii) and \( u_h \to u_\ast \) in \( X \) as \( h \to 0 \). Since \( A_h^{-1} f_h(u_\ast) = f_h(u_\ast) = (I - P_h)u_\ast \), (a) and (c) imply (2.2). So, (iii) holds. In view of (d) and (e), we have (i) with

\[
R_\ast := \sup \left\{ R > 0; \overline{B(u_\ast; R)} \subset U \text{ and } \hat{d}(R) < \frac{1}{4\|A^{-1}\|} \right\}.
\]

(4.2)

where \( \hat{d}(R) := \sup \{\|\varphi'(v) - \varphi'(u_\ast)\|; v \in U \cap \overline{B(u_\ast; R)}\} \). The proof is complete.

Proof of Theorem 2.4. We set \( u(s, h) := (1 - s)u_h + su_\ast \) for simplicity. Proposition 2.1 (iii) implies \( \max_{s \in [0, 1]}\|u_\ast - u(s, h)\| = \|u_\ast - u_h\| \to 0 \) as \( h \to 0 \). First we show (2.6). We have \( f(u_h) = -(I - P_h)\varphi(u_h) = (I - P_h)f(u_h), A_h^{-1} \to A^{-1} \) in \( \mathcal{L}(X) \) as \( h \to 0 \) and

\[
m_h := \max_{s \in [0, 1]}\|A_h - f'(u(s, h))\|
\]

\[
\leq \|A_h - A\| + \max_{s \in [0, 1]}\|f'(u_\ast) - f'(u(s, h))\| \to 0 \quad \text{as} \quad h \to 0.
\]

(4.3)
Since $A_h f(u_h) = f(u_h)$, we have $A_h^{-1} f(u_h) = f(u_h)$. We apply Proposition 3.4 with $L := A_h$, $u := u_h$, $v := u_*$ and $F := f$ to obtain

$$\frac{\|f(u_h)\|}{1 + m_h \|A_h^{-1}\|} \leq \|u_h - u_*\| \leq \frac{\|f(u_h)\|}{1 - m_h \|A_h^{-1}\|} \quad \text{for small } h > 0,$$

which implies $\|u_h - u_*\| \approx \|f(u_h)\|$. We also have $\|u_h - u_*\| \approx \|A^{-1} f(u_h)\|$ by the above discussion with $L := A_h$ replaced by $L := A$. Next, we show (2.7). In the same way as above we apply Proposition 3.4 with $L := A$ (resp., $L := A_h$), $u := u_h$, $v := P_h u_*$ and $F := f_h$ to have

$$\|P_h u_* - u_h\| \approx \|A^{-1} f_h(P_h u_*)\| \quad \text{(resp., } \|P_h u_* - u_h\| \approx \|A_h^{-1} f_h(P_h u_*)\|).$$

Since $f_h(P_h u_*) = P_h f(P_h u_*)$ and $A_h$ commutes with $P_h$, we have $\|P_h u_* - u_h\| \approx \|P_h A_h^{-1} f(P_h u_*)\|$. Combining (4.5) and $f_h(P_h u_*) = P_h (\phi(u_*) - \phi(P_h u_*))$, we obtain $\|P_h u_* - u_h\| \approx \|P_h (\phi(u_*) - \phi(P_h u_*))\|$. \qed

**Proof of Theorem 2.5.** We set $u_*(s, h) := (1 - s) u_* + s P_h u_*$ for simplicity.

(i) It follows from (H2) and Proposition 3.1 that

$$\|\phi'(u_*)(I - P_h)\| \to 0.$$  

By (H1) and the continuity of $\phi'(u)$ at $u = u_*$ we have

$$\sup_{s \in [0,1]} \|\phi'(u_*) - \phi'(u_*(s, h))\| \to 0 \quad \text{as } h \to 0.$$  

We obtain (2.8) from (4.6) and (4.7).

(ii) In the same way as (3.11) we have

$$\phi(u_*) - \phi(P_h u_*) = \int_0^1 \phi'(u_*(s, h)) ds (I - P_h) u_*.$$  

By this equality, (2.7) and (2.9), we have (2.10). \qed

Finally we derive (2.11) and (2.12).

*Proof of (2.11) and (2.13).* Without loss of generality we assume $\tilde{\epsilon}_h = \sqrt{\bar{\eta}_h^2 + 2\tilde{\eta}_h}$. First we derive (2.11). This proof is essentially the same as that of [1, Theorem 3.2]. It suffices to prove

$$\|u_* - u_h\| \leq (1 + \eta_h) \|(I - P_h) u_*\|,$$  

(4.9)
which implies (2.11) in view of \( \|u_* - u_h\|^2 = \|P_h u_* - u_h\|^2 + \|(I - P_h) u_*\|^2 \). We have

\[
A(u_h - u_*) + (I - P_h) T (u_h - u_*) - P_h T (I - P_h) (u_h - u_*) \\
- P_h \{ \varphi(u_h) - \varphi(u_*) - T (u_h - u_*) \} \\
= - A(I - P_h) u_* - (I - P_h) T (I - P_h) u_*
\]

It follows that

\[
\|u_h - u_*\| \leq (p_h + q_h + r_h) \|u_h - u_*\| + (1 + p_h) \|(I - P_h) u_*\|,
\]

which implies (4.9). Next we derive (2.13). Since \( A^{-1} = I + K \) with \( K := T(I - T)^{-1} \), we obtain from Proposition 3.1 that

\[
\left\| A^{-1}(I - P_h) T - (I - P_h) T \right\| = \|K(I - P_h) T\| \leq \|K(I - P_h)\| \|(I - P_h) T\| \\
= o(1) \|(I - P_h) T\| \quad \text{as } h \to 0.
\]

So, (2.13) holds. \( \square \)

5. Concrete Examples

In this section we consider the following semilinear elliptic boundary value problem:

\[
-\Delta u = G(x, u, \nabla u) \quad \text{in } \Omega \text{ with } u = 0 \text{ on } \partial \Omega,
\]

where \( \Omega \) is a bounded convex domain in \( \mathbb{R}^N (N \leq 3) \) with piecewise smooth boundary \( \partial \Omega \). We will rewrite (5.1) as the form (1.1) under the appropriate setting of functional spaces. We simply denote \( G(u) := G(\cdot, u, \nabla u) \). We assume \( G \in C^1(H^1_0(\Omega), H^{-1}(\Omega)) \). Let \( L \in \mathcal{L}(H^1_0(\Omega), H^{-1}(\Omega)) \) be the operator defined by \( Lu := -\Delta u \). We set \( X := H^1_0(\Omega) \) with the norm \( \|u\|_X := \|\nabla u\|_{L^2(\Omega)} \) and \( \varphi(u) := L^{-1} G(u) \). Then, we have \( \varphi, f \in C^1(X, X) \). We can rewrite (5.1) as \( f(u) = 0 \). We choose \( X_h \) as an approximate finite element subspace of \( X \) with mesh size \( h \).

In what follows, we concentrate on the cases: \( \Omega = (0, 1) \subset \mathbb{R} \) and \( \Omega = (0, 1) \times (0, 1) \subset \mathbb{R}^2 \). We use finite element methods with piecewise linear and bilinear elements on the uniform (rectangular) mesh with mesh size \( h = 1/n (n \in \mathbb{N}) \). Then, we have \( \dim X_h = n - 1 \) in the 1-dimensional case and \( \dim X_h = (n-1)^2 \) in the 2-dimensional case. In this context the following basic estimates hold:

\[
\|(I - P_h) u\|_{L^2(\Omega)} \leq C_{\lambda} h \|u\|_X \quad \text{for any } u \in X, \tag{5.2a}
\]

\[
\|(I - P_h) u\|_{X} \leq C_{\lambda} h \|\Delta u\|_{L^2(\Omega)} \quad \text{for any } u \in X \cap H^2(\Omega), \tag{5.2b}
\]

\[
\|(I - P_h) u\|_{L^\infty(\Omega)} \leq C_{\mu} h \|\Delta u\|_{L^2(\Omega)} \quad \text{for any } u \in X \cap H^2(\Omega), \tag{5.2c}
\]
where \( C_a, C_b, \) and \( C_c \) are some positive constants independent of \( h \) and \( u \). As in previous sections, we denote by \( u_\star \) an isolated solution of \( f(u) = 0 \) and by \( u_h \) a finite element solution of \( f(u) = 0 \) (i.e., a solution of \( \tilde{f}_h(u) = 0 \) in a small neighborhood of \( u_\star \)). In view of Proposition 2.1, \( u_h \) exists uniquely in a small neighborhood of \( u_\star \) for sufficiently small \( h > 0 \). In our examples below we show that the following error estimate holds:

\[
\|P_h u_\star - u_h\| = O\left(h^2\right) \quad \text{as } h \to 0. \tag{5.3}
\]

For simplicity we denote \( u_\star(s, h) := (1-s)u_\star + sP_h u_\star \). We will derive (5.3) from Theorem 2.5 and the duality

\[
\|\psi'(u_\star(s, h))(I-P_h)\| = \|(I-P_h)\psi'(u_\star(s, h))^*\|. \tag{5.4}
\]

We now present two examples.

**Example 5.1.** We consider the following Burgers equation:

\[
-\Delta u + uu_x = g \quad \text{in } \Omega := (0, 1) \times (0, 1) \quad \text{with } u = 0 \quad \text{on } \partial \Omega. \tag{5.5}
\]

Here, \( g(x,y) \) is a given function with \( g \in L^2(\Omega) \). As mentioned above, we rewrite (5.5) as \( f(u) := u - \varphi(u) = 0 \). In the present case \( \varphi : X \to X \) is a nonlinear map defined by \( \varphi(u) := L^{-1}(-uu_x + g) \). By the elliptic regularity property we have \( u_\star \in H^2(\Omega) \) (see e.g., [9]). We will derive (5.3). Let \( u, v \in X \). We easily verify that

\[
\psi'(v)u = -L^{-1}(vu_x + v_x u), \quad \psi'(v)^*u = L^{-1}(vu_x) \quad \text{for any } u \in X. \tag{5.6}
\]

By (5.2b) we have

\[
\| (I-P_h)\psi'(u_\star(s, h))^*u \| \leq C_b h \| u_\star(s, h)u_x \|_{L^2(\Omega)} \leq C_b h \| u_\star(s, h)\|_{L^\infty(\Omega)} \|u\|_X. \tag{5.7}
\]

It follows that

\[
\| (I-P_h)\psi'(u_\star(s, h))^*\| \leq C_b h \| u_\star(s, h)\|_{L^\infty(\Omega)}. \tag{5.8}
\]

We obtain from (5.2c) that

\[
\| u_\star(s, h)\|_{L^\infty(\Omega)} \leq \| u_\star\|_{L^\infty(\Omega)} + C_c hs \| \Delta u_\star\|_{L^2(\Omega)}. \tag{5.9}
\]

It follows from (5.4), (5.8), and (5.9) that

\[
\sup_{s \in [0,1]} \|\psi'(u_\star(s, h))(I-P_h)\| \leq C_b h \left( \| u_\star\|_{L^\infty(\Omega)} + C_c h \| \Delta u_\star\|_{L^2(\Omega)} \right) := \varepsilon_h. \tag{5.10}
\]

By (5.10), (5.2b), and Theorem 2.5 we have (5.3).
Remark 5.2. We consider the Emden equation

\[-\Delta u = u^2 \quad \text{in } \Omega := (0,1) \times (0,1) \text{ with } u = 0 \text{ on } \partial\Omega.\]  

(5.11)

We omit the one-dimensional case since it is easier. We can treat the present case in a similar way to Example 5.1. We rewrite (5.11) as (1.1). In the present case \( \varphi : X \rightarrow X \) is defined by \( \varphi(u) := L^{-1}(u^2) \). Let \( u, v \in X \). We verify that \( \varphi'(v)u = 2L^{-1}(vu) \) and that \( \varphi'(v) \) is self-adjoint. By (5.2b) and Sobolev’s inequality we have

\[
\|(I - P_h)\varphi'(u_*(s,h))u\| \leq 2C_h \|u_*(s,h)\|_{L^2(\Omega)} \|u\|_{L^2(\Omega)} \\
\leq Ch\|u_*(s,h)\|\|u\| \leq Ch\|u_\ast\|\|u\| 
\]

(5.12)

for any \( s \in [0,1] \) and \( u \in X \). Here, \( C > 0 \) is a constant independent of \( s, h, \) and \( u \). It follows from this inequality and (5.4) that

\[
\sup_{s \in [0,1]} \|\varphi'(u_*(s,h))(I - P_h)\| \leq Ch\|u_\ast\| := \varepsilon_h. \tag{5.13}
\]

By (5.13), (5.2b), and Theorem 2.5 we have (5.3).

Remark 5.3. This remark is related to Remark 2.6.

(i) As mentioned in Remark 2.6(ii), \( \sup_{s \in [0,1]} \|\varphi'((1-s)u_\ast + sP_h u_\ast)(I - P_h)\| \approx \|T(I - P_h)\| \) holds in general. Actually, in Example 5.2 (resp., Example 5.1) our best possible upper bound of \( \sup_{s \in [0,1]} \|\varphi'(u_*(s,h))(I - P_h)\| \) is the right-hand side of (5.13) (resp., (5.10)), which is just the same (resp., has the same order) as that of \( \|T(I - P_h)\| \).

(ii) We pointed out that our estimate (2.10) is in general sharper than (2.11), which is directly derived from the discussion in [1]. In order to show it concretely, we apply (2.11) to the equations in Examples 5.1 and 5.2. In both cases our best possible error estimate is the following:

\[
\|P_h u_\ast - u_h\| = O(h^{3/2}) \quad \text{as } h \rightarrow 0. \tag{5.14}
\]

Compare (5.14) with (5.3), which is based on (2.10). Though we omit the detailed derivation of (5.14), we show here that we cannot obtain a better estimate than (5.14) if we use (2.11) as a basic estimate. By the same discussion in Examples 5.1 and 5.2 we have

\[
\|(I - P_h)\varphi'(u_\ast)\| = O(h) \quad \text{as } h \rightarrow 0, \tag{5.15}
\]

which is our best possible upper estimate of \( \|(I - P_h)T\| \). So, in view of (2.13), it is necessary to take \( \tilde{\varepsilon}_h \) such that \( \tilde{\varepsilon}_h \geq Ch^{1/2} \) for small \( h \). Here, \( C > 0 \) is a constant independent of \( h \). (Compare this estimate with (5.10) and (5.13).) Therefore, we cannot improve (5.14) if we use (2.11) and (5.2b) as basic estimates.

Remark 5.4. Various numerical verification algorithms for solutions of differential equations were proposed up to now (see e.g., [10]). Some of them give upper bounds of \( \|P_h u_\ast - u_h\| \) as
output data (see [5]). Theorem 2.5 may be applicable for checking the accuracy of such output upper bounds since we can apply it to given problems in order to compute the concrete order of \( \| P_h u_* - u_h \| \) as \( h \to 0 \). For example, we treated problems (5.5) and (5.11) as concrete numerical examples in [5], where we proposed a numerical verification algorithm based on a convergence theorem of Newton’s method. In these problems (5.3) is the theoretical estimate of \( \| P_h u_* - u_h \| \) derived from our Theorem 2.5. The output data as upper bounds of \( \| P_h u_* - u_h \| \) in [5, Section 3] seem to have just the order of \( h^2 \) as \( h \to 0 \). So, the accuracy of such output upper bounds in [5, Section 3] is satisfactory as long as we judge it by the theoretical estimate (5.3).

Acknowledgments

The author would like to express his sincere gratitude to Professor Takuya Tsuchiya and Professor Atsushi Yagi for their valuable comments and encouragement. He is grateful to the referee for constructive comments.
