Based on characteristics of the nonlife joint-stock insurance company, this paper presents a compound binomial risk model that randomizes the premium income on unit time and sets the threshold \( x \) for paying dividends to shareholders. In this model, the insurance company obtains the insurance policy in unit time with probability \( p_0 \) and pays dividends to shareholders with probability \( p_1 \) when the surplus is no less than \( x \). We then derive the recursive formulas of the expected discounted penalty function and the asymptotic estimate for it. And we will derive the recursive formulas and asymptotic estimates for the ruin probability and the distribution function of the deficit at ruin. The numerical examples have been shown to illustrate the accuracy of the asymptotic estimations.

1. Introduction

The compound binomial risk model is one of the classical actuarial models that have been studied extensively. The classic literatures about the compound risk model primarily include [1–9]. With the emergence and development of dividend insurance, compound binomial risk models considering the case of paying dividends to policyholder are attracting more and more attention of actuarial scholars; see [10–14]. Reference [10] builds the compound binomial risk model with randomly dividends payment and derives the ruin problem by recursive algorithm for cases where the company pays dividends to its policyholders with a certain probability. Reference [11] obtains and solves two defective renewal equations for the Gerber-Shiu penalty function under the compound binomial model proposed in [10]. Reference [12] generalizes the model of [10] and derives the discounted penalty function under the compound binomial model with a multi-threshold dividend structure and randomized dividend payments. Considering the fact that the joint-stock company may pay dividends to the policyholders and shareholders, [13] builds the compound binomial risk model with random dividends payment to the policyholders and shareholders and studies the ruin problem with the model. Furthermore, [14] derives the arbitrary moments of discounted dividend payments under the compound binomial risk model with interest on the surplus and periodically paying dividend.

The previously mentioned models are compound binomial risk models with a constant premium rate suited for depicting the surplus of the life insurance companies which collect installment premiums. However, nonlife insurance companies (e.g., property insurance companies) charge premiums immediately, and insurance policies are obtained randomly in unit time. Thus the model with a constant premium rate cannot reasonably describe the surplus of the nonlife insurance companies. Moreover, joint-stock nonlife insurance companies need to pay dividends to the shareholders randomly (see [10]). However, these characteristics have not been considered in [10] together. Thus, [10] cannot be suitable for describing the surplus of the joint-stock nonlife insurance companies. In order to address the deficiencies of the models in [10], a compound binomial risk model has been developed with random premiums and dividends payment to shareholders, and it derives the recursive formulas and asymptotic estimates of the ruin probability and the distribution of the deficit at ruin.

This paper is organized as follows. In Section 2, we build the compound binomial risk model with randomly charging premiums and paying dividends to shareholders. In Section 3, we derive the recursive formulas of discounted penalty
function. In Section 4, we derive the asymptotic estimates for the discounted penalty function. In Section 5, we obtain recursive formulas, and asymptotic estimates of the ruin probability and the distribution function of deficit at ruin are obtained. Finally, the conclusion is shown in Section 6.

2. The Model and Preliminaries

Consider the compound binomial model with randomized decisions on paying dividends, which is described by

\[ U(t) = u + t - S(t) - D(t), \quad t = 1, 2, \ldots \]  

(1)

with the initial surplus of the insurance \( u \geq 0 \). \( S_t \) is the aggregate claim up to time \( t \); that is,

\[ S(t) = \sum_{k=1}^{t} \theta_k X_k, \quad t = 1, 2, \ldots \]  

(2)

where \( \theta_k \) denotes whether the claim occurs or not in \( (t-1, t] \); the event in which the claim occurs is denoted by \( \theta_{t+1} = 1 \); the event in which no claim is denoted by \( \theta_{t+1} = 0 \). The probability of a claim is \( p \) and the probability of no claim is \( q = 1 - p \) in any period \( (t, t+1] \). \( \theta = \{ \theta_t, t = 1, 2, \ldots \} \) is independent and identically distributed random series. \( X = \{ X_t, t = 1, 2, \ldots \} \) is independent and identically distributed as \( F = \{ p(k) = \Pr(X = k); k = 1, 2, \ldots \} \). \( D(t) \) is the aggregate dividends payment; that is,

\[ D(t) = \sum_{k=1}^{t} q_k I(U(k-1) \geq x), \quad t = 1, 2, \ldots \]  

(3)

where \( x > 0 \) is the threshold such that the insurance company may pay dividends to the shareholders, and \( I(B) \) is the indicator function of a set \( B \). \( e_k \) denotes whether dividend is paid or not in \( (t-1, t] \). When the surplus is no less than \( x \), the company pays one dividend to the shareholders with probability \( p_1 \) (denoted by \( e_k = 1 \)) and not with the probability \( q_1 = 1 - p_1 \) (denoted by \( e_k = 0 \)); \( e = \{ e_k, t = 1, 2, \ldots \} \) is independent and identically distributed as \( B(p_1) \) \( (0 < p_1 < 1) \).

According to the feature of the variety of the surplus in joint-stock nonlife insurance companies, we further assume that premium is charged randomly in unit period \( (t-1, t] \). Then the aggregate premium is

\[ M(t) = \sum_{k=1}^{t} I_k, \quad t = 1, 2, \ldots \]  

(4)

where \( I_k \) is variable with distribution \( B(p_0) \) \( (0 < p_0 \leq 1) \), \( q_0 = 1 - p_0 \), and denotes obtaining an insurance policy by \( I_k = 1 \) in \( (t-1, t] \), as well as denotes not obtaining an insurance policy by \( I_k = 0 \). \( I = \{ I_t, t = 1, 2, \ldots \} \) is independent and identically distributed. Furthermore, the random series \( \theta, X, e, I \) are assumed to be mutually independent. Then, the surplus of the nonlife insurance joint-stock company is

\[ U(0) = u \]  

(5)

\[ U(t) = u + M(t) - S(t) - D(t), \quad t = 1, 2, \ldots \]  

(6)

The model is called as the compound binomial risk model with random premiums and dividends payment to shareholders.

Remark. (1) Model (5) is the general form of the model in [10] and is the model in [10] if \( p_0 = 1 \). And also, model (5) can be regarded as general form of the classic risk model and exactly the classic risk model if \( p_0 = 1, p_1 = 0 \).

(2) In this model, the initial time \( t = 0 \) is some time in the past at which point we begin studying the surplus of the joint-stock nonlife insurance company, but not the time when the company is created.

Define ruin time with \( T = \inf\{ t \geq 0 \mid U(t) < 0 \} \). The ultimate ruin probability is defined by \( \psi(u) = \Pr(T < +\infty \mid U(0) = u) \). Define the (expected discounted) penalty function by

\[ \phi_r(u) = E\left[ f(U_{T-1}, U_T) \mid I(T < +\infty) \right] r^T \mid U(0) = u \]  

(7)

where \( f(x, y) \) \( (x \geq 0, y \geq 0) \) is the non-negative bounded function, \( 0 < r \leq 1 \). In this paper, the fact that \( \sum_{k=0}^{+\infty} m_k = 0 \) is adopted.

Let \( P(n) = \sum_{k=1}^{n} p(k), \bar{P}(n) = 1 - P(n) \). We always assume that \( \mu = \sum_{k=1}^{+\infty} kp(k) = \sum_{k=1}^{+\infty} \bar{P}(n) < +\infty \), and the \( E[I_k - \theta_k X_k - e_k] = p_0 - p_\mu - p_1 > 0 \), which leads to the positive security loading. Denote that the security loading \( \delta : \delta = (p_0 - p_\mu - p_1)/p_\mu > 0 \). Let \( \phi(u) = \phi_1(u) \).

3. The Recursive Formulas of the Penalty Function

Theorem 1. Let \( I(x) = q_0 p_1 p(x) + (q_0 q_1 + p_0 p_1) p(x+1) + p_0 q_1 p(x+2), \bar{I}(x) = q_0 p_1 \bar{P}(x) + (q_0 q_1 + p_0 p_1) \bar{P}(x+1) + p_0 q_1 \bar{P}(x+2) \), \( T(x) = p_0 p(x+1) + q_0 p(x), \bar{T}(x) = p_0 \bar{P}(x+1) + q_0 \bar{P}(x) \). Then

\( (1) \phi(0), \phi(1), \ldots, \phi(x) \) satisfy the following linear equations:

\[ p_0 q \phi(0) - p_1 \phi(x-1) = \alpha, \]  

(8)

\[ p_0 q \phi(u+1) + (q_0 + pp_0 p(1-1)) \phi(u) \]  

\[ + p \sum_{k=0}^{u-1} \phi(k) T(u-k) = \beta, \quad u = 0, 1, 2, \ldots, x-1, \]  

(9)

where

\[ \alpha = p_1 q_1 \sum_{k=0}^{x-1} \sum_{i=k+1}^{+\infty} f(k, i-k) T(i) \]  

\[ + pp_1 \sum_{k=0}^{x-2} \sum_{i=k+1}^{+\infty} f(k, i-k) T(i) \]
\[
\beta = -p \sum_{k=x+1}^{\infty} f(k, k-u) J(k); \tag{10}
\]

(2) for \( u \geq x \), the penalty functions \( \phi(u) \) satisfy

\[
\phi(u+1) = q_0 q \phi(u) + \frac{p_0 p_1}{q_0 q_1} \phi(u) - \frac{q_0 p_1}{q_0 q_1} \phi(u-1)
- \frac{p}{q_0 q_1} \sum_{k=0}^{u} \phi(k) J(u-k-1)
- \frac{p}{q_0 q_1} \sum_{k=u+1}^{\infty} f(u, k-u) J(k-1), \tag{11}
\]

\[
\phi(u+1) = \frac{q_0 p_1}{p_0 q_1} \phi(u) + \frac{p}{q_0 q_1} \sum_{k=0}^{u} \phi(k) J(x-k-1)
+ \frac{p}{q_0 q_1} \sum_{k=0}^{\infty} \sum_{i=k+1}^{\infty} f(k, i-k) J(i-1). \tag{12}
\]

Proof. Considering the insurance policy and dividend and claim number in the first time period \((0,1]\), there are twelve cases as follows:

(1) no insurance policy is obtained, no claim occurs, and no dividend is paid in \((0,1]\);
(2) an insurance policy is obtained, no claim occurs, and no dividend is paid in \((0,1]\);
(3) no insurance policy is obtained, a claim occurs, no dividend is paid, and \(U(1) \geq 0\) in \((0,1]\);
(4) an insurance policy is obtained, a claim occurs, no dividend is paid, and \(U(1) \geq 0\) in \((0,1]\);
(5) no insurance policy is obtained, a claim occurs, no dividend is paid, and \(U(1) < 0\) in \((0,1]\);
(6) an insurance policy is obtained, a claim occurs, no dividend is paid, and \(U(1) < 0\) in \((0,1]\);
(7) no insurance policy is obtained, no claim occurs, and a dividend is paid in \((0,1]\) (if \(U(0) < x\), the case does not exist);
(8) an insurance policy is obtained, no claim occurs, and a dividend is paid in \((0,1]\) (if \(U(0) < x\), the case does not exist);
(9) no insurance policy is obtained, a claim occurs, and a dividend is paid in \((0,1]\) (if \(U(0) < x\), the case does not exist);
(10) an insurance policy is obtained, a claim occurs, a dividend is paid, and \(U(1) \geq 0\) in \((0,1]\) (if \(U(0) < x\), the case does not exist);
(11) no insurance policy is obtained, a claim occurs, a dividend is paid, and \(U(1) \geq 0\) in \((0,1]\) (if \(U(0) < x\), the case does not exist);
(12) an insurance policy is obtained, a claim occurs, a dividend is paid, and \(U(1) < 0\) in \((0,1]\) (if \(U(0) < x\), the case does not exist).

Using the total probability formula, when \(0 \leq u < x\),

\[
\phi(u) = q_0 q \phi(u) + p_0 q \phi(u+1) + \sum_{k=0}^{u} \phi(k) T(u-k)
+ p \sum_{k=u+1}^{\infty} f(u, k-u) T(k). \tag{13}
\]

Equation (13) is equivalent to (9).

When \(u \geq x\),

\[
\phi(u) = q_0 q \phi(u) + q_0 p_1 \phi(u-1)
+ p_0 q_1 \phi(u+1) + p \sum_{k=0}^{u} \phi(k) J(u-k-1)
+ p \sum_{k=u+1}^{\infty} f(u, k-u) J(k-1). \tag{14}
\]

Equation (11) comes from (14). Equation (14) is equivalent to

\[
[1 - q(q_0 q_1 + p_0 p_1)] \phi(u) = q_0 p_1 \phi(u-1)
+ q_0 q_1 \phi(u+1)
+ p \sum_{k=0}^{u} \phi(k) J(u-k-1)
+ p \sum_{k=u+1}^{\infty} f(u, k-u) J(k-1). \tag{15}
\]

Subtracting \(q(q_0 q_1 + p_0 q_1)\phi(u)\) from (15), we obtain

\[
p \phi(u) = q_0 q_1 (\phi(u-1) - \phi(u))
+ q_0 q_1 (\phi(u+1) - \phi(u))
+ p \sum_{k=0}^{u} \phi(k) J(u-k-1)
+ p \sum_{k=u+1}^{\infty} f(u, k-u) J(k-1). \tag{16}
\]

When \(t \geq x\), summing (16) over \(u\) from \(x\) to \(t\) yields

\[
p \sum_{u=x}^{t} \phi(u) = q_0 q_1 (\phi(x-1) - \phi(x))
+ q_0 q_1 (\phi(t+1) - \phi(x)).
\]
Journal of Applied Mathematics

\[ + p \sum_{u=x}^{t} \sum_{k=0}^{u} \phi(k) J(u-k-1) \]
\[ + p \sum_{u=x}^{t} \sum_{k=u+1}^{+\infty} f(u,k-u) J(k-1). \]  

(17)

Interchanging the summing order of the third term in the right-hand side of (17), we get

\[ p \sum_{u=x}^{t} \sum_{k=0}^{u} \phi(k) J(u-k-1) \]
\[ = p \sum_{k=0}^{t} \phi(k) \left(1 - \overline{J}(t-k-1)\right) \]
\[ - p \sum_{k=0}^{x-1} \phi(k) \left(1 - \overline{J}(x-k-2)\right). \]  

(18)

Adding (18) to (17), we obtain

\[ q q_0 \psi_1 (\phi(x) - \phi(t)) + q q_0 q_1 (\phi(t+1) - \phi(x)) \]
\[ = p \sum_{k=0}^{t} \phi(k) \overline{J}(t-k-1) - p \sum_{k=0}^{x-1} \phi(k) \overline{J}(x-k-2) \]
\[ - p \sum_{u=x}^{t} \sum_{k=u+1}^{+\infty} f(u,k-u) J(k-1). \]  

(19)

The security loading \( \delta > 0 \) leads to \( \lim_{u \to +\infty} \psi(u) = 0 \). \( f(x,y) \) is bounded function, \( \phi(u) \leq \psi(u)\|f\| \), where \( \|f\| = \sup \{f(x,y) \mid x \in N, y \in N\} \). Therefore, \( \lim_{u \to +\infty} \phi(u) = 0 \). By the Dominated Convergence Theorem, we can obtain

\[ p \sum_{k=0}^{t} \phi(k) \overline{J}(t-k-1) \]
\[ \leq p \sum_{k=1}^{t+1} \phi(t+1-k) \overline{J}(k-2) \]
\[ \leq p \sum_{k=1}^{+\infty} \phi(t+1-k) \overline{J}(k-2) \to 0 \quad (t \to +\infty). \]  

(20)

Let \( t \to +\infty \) in (19), and we get

\[ q q_0 \psi_1 (\phi(x) - \phi(t)) - q q_0 q_1 \phi(x) \]
\[ = -p \sum_{k=0}^{x-1} \phi(k) \overline{J}(x-k-2) \]
\[ - p \sum_{u=x}^{+\infty} \sum_{k=u+1}^{+\infty} f(u,k-u) J(k-1). \]  

(21)

Subtracting (21) from (19)

\[ - q q_0 \psi_1 \phi(t) + q q_0 q_1 \phi(t+1) \]
\[ = p \sum_{k=0}^{t} \phi(k) \overline{J}(x-k-1) \]
\[ + p \sum_{k=0}^{+\infty} \sum_{i=k+1}^{+\infty} f(k,i-k) J(i-1). \]  

(22)

Equation (12) is equivalent to (22).

Subtracting \( p \phi(u) \) from both sides of (13), we obtain

\[ p \psi(u) = p q \left(\psi(u+1) - \psi(u)\right) + p \sum_{k=0}^{u} \phi(k) T(u-k) \]
\[ + p \sum_{k=0}^{u} f(u,k-u) T(k). \]  

(23)

When \( x \geq 1 \), summing (23) over \( u \) from 0 to \( x-1 \), we get

\[ p \sum_{u=0}^{x-1} \phi(u) = p q \left(\psi(x) - \psi(0)\right) + p \sum_{k=0}^{x-1} \sum_{u=0}^{k} \phi(k) T(u-k) \]
\[ + p \sum_{u=0}^{x-1} \sum_{k=0}^{+\infty} f(u,k-u) T(k). \]  

(24)

Interchanging the summation order of the second term on the right-hand side of (24), (24) is equivalent to

\[ p q \left(\psi(x) - \psi(0)\right) = p \sum_{k=0}^{x-1} \phi(k) \overline{J}(x-1-k) \]
\[ - p \sum_{u=0}^{x-1} \sum_{k=0}^{+\infty} f(u,k-u) T(k). \]  

(25)

Replacing \( x \) by \( x-1 \) and adding \( p \psi(x-1) \) to both sides of (25), we yield

\[ p q \left(\psi(x) - \psi(0)\right) + p \psi(x-1) \]
\[ = p \sum_{k=0}^{x-1} \phi(k) \overline{J}(x-1-k) \]
\[ - p \sum_{u=0}^{x-2} \sum_{k=0}^{+\infty} f(u,k-u) J(k). \]  

(26)

From (25) \times (21) + (25) \times (26), we obtain

\[ q p q_1 \psi_1 \phi(x) + \left( q p q_1 \phi(x) - q q_0 q_1 \phi(0) \right) \]
\[ = p \sum_{k=0}^{x-1} \phi(k) \overline{J}(t-k-2) + p q q_1 \sum_{k=0}^{x-1} \sum_{i=k+1}^{+\infty} f(k,i-k) J(i) \]
\[ - p \sum_{k=0}^{x-2} \sum_{i=k+1}^{+\infty} f(k,i-k) J(i). \]  

(27)

Equation (27) minus (21) is (9). The theorem has been proved.
According to Theorem 1, \( \phi(0), \phi(1), \ldots, \phi(x - 1) \) can be obtained by solving the linear equations (8) and (9) when \( x \geq 1 \). And we can obtain \( \phi(x + 1), \phi(x + 2), \ldots \) by (11). The following problem that needs to be solved is whether there is a unique solution to the set of linear equations (8) and (9).

**Definition 2.** Assume that the matrix \( A = (a_{ij}) \in C^{n \times n} \), and it satisfies

\[
|a_{ii}| > \sum_{j \neq i} |a_{ij}|	ag{28}
\]

Then \( A \) is called a (row) strictly diagonally dominant matrix.

**Lemma 3.** If \( A \) is a strictly diagonally dominant matrix, then \( A \) is a nonsingular matrix.

**Proof.** For the proof, see [6]. \( \square \)

**Theorem 4.** Under the assumption that the security loading \( \delta > 0 \), the set of linear equations (8) and (9) have a unique solution.

**Proof.** Let \( \phi = (\phi(0), \phi(1), \phi(2), \ldots, \phi(x)) \), \( \Delta = (\alpha, \beta(0), \beta(1), \beta(2), \ldots, \beta(x)) \), \( \chi = q\gamma_0 + pp_0p(1) - 1, \chi' = pp_0p(1) - p \), then, the set of linear equations (8) and (9) can be rewritten as

\[
B\phi = \Delta.	ag{30}
\]

The coefficient matrix \( B \) will be carried out by a series of elementary row operations as follows: the \((x + 1)\) row is replaced by itself plus the first \( x \) rows; the \( x \) row is replaced by itself plus the first \( x - 1 \) rows, and so on; the second row is replaced by itself plus the first row. The matrix \( B \) is changed into

\[
\begin{pmatrix}
p_0q & 0 & 0 & 0 & \cdots & 0 & 0 & -p_1 & 0 \\
p' & p_0q & 0 & 0 & \cdots & 0 & 0 & -p_1 & 0 \\
pT(1) & p_0q & 0 & 0 & \cdots & 0 & 0 & -p_1 & 0 \\
pT(2) & pT(1) & p_0q & 0 & \cdots & 0 & 0 & -p_1 & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
pT(x - 1) & pT(x - 2) & pT(x - 3) & pT(x - 4) & \cdots & pT(1) & \chi & p_0q
\end{pmatrix};
\tag{29}
\]

For the first row, because \( \delta > 0 \) and \( \mu = \sum_{n=0}^{+\infty} \overline{T}(n) > 1 \),

\[
p_0q - p_1 = p_0(1 - p) - p_1 > p_0 - p_1 - \mu > 0. \tag{32}
\]

For the second row, because \( q_0q + pp_0p(1) - 1 < 0 \), then

\[
p_0q - \left|\chi'\right| - p_1 = p_0 - pp_0p(1) - p - p_1 > p_0 - p \left(\overline{T}(1) + \overline{T}(0)\right) - p_1 > p_0 - p\mu - p_1 > 0. \tag{33}
\]

For the \( i \) row (\( 2 < i \leq x - 1 \)),

\[
p_0q - p \sum_{k=1}^{i-2} \overline{T}(k) + pp_0p(1) - p - p_1
\]

\[
= p_0 - pp_0 \sum_{k=1}^{i-1} \overline{T}(k) - pp_0 \sum_{k=1}^{i-2} \overline{T}(k) - p - p_0
\]

\[
\geq p_0 - pp_0 (\mu - 1) - pp_0 (\mu - 1) - p - p_0
\]

\[
= p_0 - p\mu - p_1 > 0. \tag{34}
\]
For the row, owing to $p_0q - p_1 = p_0 - p_1 - pp_0 > 0$,
\[ p_0q - p_1 - \left| x' \right| - p \sum_{k=1}^{x-2} \bar{T}(k) \]
\[ = p_0 - p_0p \sum_{k=1}^{x} \bar{T}(k) - q_0p \sum_{k=1}^{x-1} \bar{T}(k) \]
\[ \geq p_0 - pp_0 (\mu - 1) - pq_0 (\mu - 1) - p - p_0 \]
\[ = p_0 - p\mu - p_1 > 0 \]  
(35)

Thus, the matrix $B$ is a strictly diagonally dominant matrix. According to Lemma 3, matrix $B$ is a nonsingular matrix. So the set of linear equations have a unique solution. The theorem has been proved. 

**4. The Asymptotic Estimate of the Penalty Function**

Let $D = \theta_1 X_1 + \epsilon_1 - 1$, denote the generating function of $D$; then
\[ G_D(r) = (pG_X + q)(p_1 r + q_1) \left( \frac{p_0}{r} + q_0 \right). \]  
(37)

where $G_X$ is the generating function of $X$.

**Assumption 5.** There exists a $r_\infty$ such that $G_X(r) \to +\infty$ ($r \to r_\infty$) ($r_\infty$ is possibly $+\infty$).

This assumption is similar to the one in [11].

Let $G_D(r) = 1$, and then
\[ (pG_X(r) + q)(p_1 r + q_1)(p_0 + q_0 r) = r. \]  
(38)

Let $H(r) = (pG_X(r) + q)(p_1 r + q_1)(p_0 + q_0 r)$. $H(0) = q_0 p_0$, $H(1) = 1$, $H(r)$ is a convex and increasing function in $[0, r_\infty]$, and thus (38) has two real nonnegative roots at most, and one of them is 1. Because $\delta > 0$, $H'(1) = 1 - (p_0 - p\mu - p_1) < 1$. Because $H''(r) > 0$ in $[0, r_\infty)$, $H(r)$ is strictly convex in $[0, r_\infty)$. Therefore, there exist two real roots in (38). Denote the other root by $R$, and then $R > 1$.

Note that if $q_0 = 0$, (38) becomes
\[ (pG_X(r) + q)(p_1 r + q_1) = r, \]  
(39)

which is just the adjustment coefficient of the compound binomial model with randomized decisions on dividends payment (see [10]). The following lemma will be used to derive the asymptotic estimates of $\phi(u)$.

**Lemma 6.** $Z$ is a set of integers, $\{a_k, k \in \mathbb{Z}\}$, $\{b_k, k \in \mathbb{Z}\}$ are sequences that satisfy $a_k \geq 0$, $\sum_{k=0}^{\infty} a_k = 1$, $\lim_{k=0}^{\infty} |a_k| < +\infty$, $\sum_{k=0}^{\infty} b_k > 0$, $\sum_{k=0}^{\infty} b_k < +\infty$, the greatest common divisor of the integers $k$ for which $a_k > 0$ is 1, and the bounded series $u_k$ satisfies the following renewal equation:
\[ u_n = \sum_{k=0}^{\infty} a_{n-k} u_k + b_n, \quad n = 0, \pm 1, \pm 2, \ldots \]  
(40)

then $\lim_{n \to -\infty} u_n$ and $\lim_{n \to +\infty} u_n$ exist. Furthermore, if $\lim_{n \to -\infty} u_n = 0$, then
\[ \lim_{n \to -\infty} u_n = \frac{\sum_{k=-\infty}^{\infty} b_k}{\sum_{k=-\infty}^{\infty} a_k}. \]  
(41)

**Proof.** The proof can be seen in Karlin and Taylor [5] (Chapter 3).

**Theorem 7.** The asymptotic estimate for the penalty $\phi(u)$ is
\[ \phi(u) \sim K R^{-u}, \]  
(42)

where
\[ K = (\left(\left[ q_0 p_1 (R^{-1}) + p_0 q R (R^x - 1)\right] \phi(0) \right. \]
\[ + (R - 1)(qq_0 p_1 - q_0 p_1 - pp_1) \sum_{m=1}^{\infty} R^m \phi(m - 1) \]
\[ + K_1 (R - 1)) \times \left( (R - 1) \left( K_2 R + p \sum_{k=2}^{\infty} f(k, i - k) J(i - k) \right) \right)^{-1}, \]
\[ K_1 = -pq_1 K_3 - pp_1 K_4 + K_5, \]
\[ K_2 = qq_0 p_1 + pp_0 q_1 + p (p_0 p_1 + q_0 q_1), \]
\[ K_3 = \sum_{m=1}^{\infty} R^m \sum_{k=0}^{m-1} \sum_{i=k+1}^{m+1} f(k, i - k) J(i), \]
\[ K_4 = \sum_{m=1}^{\infty} R^m \sum_{k=0}^{m-2} \sum_{i=k+1}^{m+1} f(k, i - k) J(i), \]
\[ K_5 = \sum_{m=1}^{\infty} R^m \sum_{k=m+1}^{\infty} f(k, i - k) J(i - 1). \]  
(43)

**Proof.** When $u > x$, from (12), we can obtain
\[ \phi(u) = (q_0 + p_0 p_1 + pp_1 q_1) \phi(u) \]
\[ + \left( qq_0 p_1 + pp_0 q_1 + p (q_0 q_1 + p_0 p_1) \right) \]
\[ \times \phi(u - 1) + p \sum_{k=0}^{u-2} \phi(k) J(u - 2 - k) \]
\[ + p \sum_{k=0}^{\infty} \sum_{i=k+1}^{\infty} f(k, i - k) J(i - 1). \]  
(44)
Equation (27) is equivalent to
\[
\phi(u) = (q_0 + p_0 p_1 + p p_1 q_1) \phi(u) \\
+ (q q_0 p_1 + p q_0 q_1) \tilde{P}(1) + q_0 p_1 p + p (q_0 q_1 + p_0 p_1) \\
\times \phi(u-1) + p \sum_{k=0}^{u-2} \phi(k) \tilde{T}(u-2-k) + p q \phi(0) \\
+ (q q_0 p_1 - p q_1 - p p_1) \phi(u-1) \\
- p q_1 \sum_{k=0}^{u-2} \sum_{i=k+1}^{+\infty} f(k, i-k) T(i) \\
- p p_1 \sum_{k=0}^{u-2} \sum_{i=k+1}^{+\infty} f(k, i-k) T(i). \\
\]
(45)

Combining (44) and (45), we can obtain the renewal equation
\[
\phi(u) = (q_0 + p_0 p_1 + p p_1 q_1) \phi(u) + (q q_0 p_1 + p q_0 q_1) \tilde{P}(1) \\
+ q_0 p_1 p + p (q_0 q_1 + p_0 p_1) \phi(u-1) \\
+ p \sum_{k=0}^{u-2} \phi(k) \tilde{T}(u-2-k) \\
+ p_{0 \phi} \phi(0) + (q q_0 p_1 - p q_1 - p p_1) \phi(u-1), \\
- p q_1 \sum_{k=0}^{u-2} \sum_{i=k+1}^{+\infty} f(k, i-k) T(i) \\
- p p_1 \sum_{k=0}^{u-2} \sum_{i=k+1}^{+\infty} f(k, i-k) T(i), \\
0 < u \leq x, \\
0 < u \leq x, \\
0 < u \leq x, \\
0 < u \leq x.
\]
(46)

Multiplying (46) by \(R^u\), we can obtain
\[
\overline{\phi}(u) = \sum_{k=0}^{u} a_{u-k} \overline{\phi}(k) + b_u, \quad u = 0, 1, 2, \ldots 
\]
(48)

We will prove that (48) satisfies the conditions of Lemma 6.

Consider
\[
\sum_{k=0}^{+\infty} a_k = q_0 + p_0 p_1 + p q_0 q_1 \\
+ (q q_0 p_1 + p q_0 q_1) \tilde{P}(1) + q_0 p_1 p + p (q_0 q_1 + p_0 p_1) \tilde{P}(1) \\
+ p \sum_{k=0}^{+\infty} f(k, i-k) T(i) \\
+ p \sum_{k=0}^{+\infty} f(k, i-k) T(i), \\
0 < u \leq x, \\
x < u.
\]
(49)

Denoting that \(a(u) = \phi(u) R^u\),
\[
a_u = \begin{cases} 
q_0 + p_0 p_1 + p p_1 q_1, & u = 0, \\
R(q q_0 p_1 + p q_0 q_1) \tilde{P}(1) + q_0 p_1 p + p (q_0 q_1 + p_0 p_1) \tilde{P}(1), & u = 1, \\
p R^u \tilde{T}(u-2), & u \geq 2,
\end{cases}
\]
(50)
where the last equation is valid because \(R\) is the root of (38). The following steps will prove that \(\sum_{k=0}^{u} b_{k} < \infty\). For \(u > x\),
\[
0 \leq b_u \geq p \|f\| R^u \sum_{k=u}^{+\infty} T(k-1); 
\]
(51)
then
\[
\sum_{u=x+1}^{+\infty} b_u \leq p \left\| \int \right\| \sum_{k=1}^{+\infty} R^k \sum_{u=x+1}^{+\infty} \mathcal{I}(k-1),
\]
\[
P \sum_{u=x+1}^{+\infty} R^k \sum_{u=x+1}^{+\infty} \mathcal{I}(k-1) = p \sum_{k=1}^{+\infty} \mathcal{I}(k-1) R^k
\]
\[
= p \sum_{k=1}^{+\infty} \mathcal{I}(k-1) \frac{R^k - R}{R - 1}
\]
\[
= \frac{p}{R(R-1)} \sum_{k=2}^{+\infty} R^k \mathcal{I}(k-2)
\]
\[
- \frac{R}{R - 1} \sum_{k=2}^{+\infty} \mathcal{I}(k-2)
\]
\[
\leq \frac{p}{R(R-1)} \sum_{k=2}^{+\infty} k a_k \leq \frac{p}{R(R-1)}.
\]
From (51), we can obtain \( \sum_{u=x+1}^{+\infty} b_u \leq +\infty \). And because \(|b_k| < +\infty (0 \leq u \leq x)\), \( \sum_{u=0}^{+\infty} b_u < +\infty \). Further, we can get
\[
\sum_{k=0}^{+\infty} b_k = \left[ q p_0 p_1 + p_0 q \frac{R(R^x - 1)}{R - 1} \phi(0) \right] + (q q_0 p_1 - q p_0 p_1 - p p_1) \sum_{m=1}^{x} R^m \phi(m - 1) + K_1
\]
\[
+ \sum_{k=1}^{+\infty} k a_k = K_2 + p \sum_{k=2}^{+\infty} k R^k \mathcal{I}(k-2).
\]
According to Lemma 6, we can derive
\[
\lim_{u \to +\infty} \mathcal{I} = \left[ q p_0 p_1 + p_0 q \frac{R(R^x - 1)}{R - 1} \phi(0) \right] + (q q_0 p_1 - q p_0 p_1 - p p_1) \sum_{m=1}^{x} R^m \phi(m - 1) + K_1
\]
\[
\times \left( K_2 R + p \sum_{k=2}^{+\infty} k \mathcal{I}(k-2) \right)^{-1}.
\]
Equation (53) is equivalent to (42). The theorem has been proved. \( \square \)

5. The Application of the Penalty Function

We will give some examples of ruin quantities such as the ultimate ruin probability, the distribution of the surplus of the deficit at ruin to illustrate the application of the recursive formulas, and asymptotic estimates for the penalty function \( \phi(u) \).

| Table 1: Adjustment coefficients. |
| P | (0.9, 0.015) | (0.75, 0.015) | (0.75, 0.055) | (0.65, 0.055) |
| R | 1.02157 | 1.01547 | 1.01274 | 1.010447 |

5.1. Ruin Quantities

Example 8. Let \( f(x, y) = 1 \), \( \phi(u) = \text{Pr}(T < +\infty \mid U(0) = u) = \psi(u) \), which is the ultimate ruin probability. By Theorem 1, we can show that
\[
(1) \; \psi(0), \psi(1), \ldots, \psi(x) \text{ satisfy the following linear equations:}
\]
\[
p_0 q \psi(0) - p_1 \psi(x - 1) = \alpha,
\]
\[
p_0 q \psi(u + 1) + (q q_0 + p p_0 p(1) - 1) \psi(u) + p \sum_{k=0}^{u-1} \psi(k) T(u-k) = \beta,
\]
\[
u = 0, 1, 2, \ldots, x - 1,
\]
where
\[
\alpha = p q_1 \sum_{k=0}^{x-1} T(k) + p p_0 \sum_{k=0}^{x-2} T(k) + p \sum_{k=0}^{+\infty} T(u-1),
\]
\[
\beta = - p T(u);
\]
\[
(2) \text{ for } u \geq x, \text{ the penalty functions } \phi(u) \text{ satisfy}
\]
\[
\psi(u + 1) = \frac{1 - q (q q_0 q_1 + p p_0 p_1)}{q p_0 q_1} \psi(u) - \frac{q p_0 p_1}{q p_0 q_1} \psi(u-1)
\]
\[
- \frac{p}{q p_0 q_1} \sum_{k=0}^{x} \psi(k) J(u-k - 1) - p \sum_{k=0}^{+\infty} J(k-1).
\]
By Theorem 7, the asymptotic estimates of the ultimate ruin probability are
\[
\psi(u) \sim K \psi R^{-u},
\]
where
\[
K = \left[ q p_0 p_1 (R - 1) + p_0 q R (R^x - 1) \right] \psi(0)
\]
\[
+ (R - 1) (q q_0 p_1 - q p_0 p_1 - p p_1)
\]
\[
\times \sum_{m=1}^{x} R^m \psi(m - 1) + K_1 (R - 1)
\]
\[
\times \left( (R - 1) \left( K_2 R + p \sum_{k=2}^{+\infty} \mathcal{I}(k-2) \right) \right)^{-1},
\]

\[
K_1 = -pq_1 K_3 - pp_1 K_4 + K_5,
\]

\[
K_2 = q_0 p_1 + pp_0 q_1 F(1) + p q_0 p_1 + p (p_0 p_1 + q_0 q_1),
\]

\[
K_3 = \sum_{m=1}^{x} R^m \sum_{k=0}^{m-1} \bar{T}(k), \quad K_4 = \sum_{m=1}^{x} R^m \sum_{k=0}^{m-2} \bar{T}(k),
\]

\[
K_5 = \sum_{m=x+1}^{\infty} R^m \bar{T}(m-1).
\]

(58)

Example 9. Let \( f(x, y) = I(y \leq z) \) \((z = 1, 2, \ldots)\), and then \( \phi(u) = \Pr((|U(T)| \leq z, T < +\infty \mid U(0) = u)) = F(u, z) \), which is the distribution of the surplus of the deficit at ruin. By Theorem 1, we can show that

1. \( F(0, z), F(1, z), \ldots, F(x-1, z) \) satisfy the following linear equations:

\[
p_0 q F(0, z) - p_1 F(x-1, z) = \alpha,
\]

\[
p_0 q F(u+1, z) + (p_0 q + pp_0 p (1-1)) F(u, z) + p \sum_{k=0}^{u-1} \phi(k) T(u-k) = \beta, \quad u = 0, 1, 2, \ldots, x-1,
\]

where

\[
\alpha = p q_1 \sum_{k=0}^{x-1} \bar{T}(k) - \bar{T}(k+z) + pp_1 \sum_{k=0}^{x-2} \bar{T}(k)
\]

\[
- \bar{T}(k+z) + p \sum_{k=x}^{\infty} \left( \bar{T}(k-1) - \bar{T}(k+z-1) \right)
\]

\[
\beta = -p \left( \bar{T}(u) - \bar{T}(u+z) \right);
\]

(60)

(2) for \( u \geq x \), the penalty functions \( \phi(u) \) satisfy

\[
F(u+1, z) = \frac{1 - q_0 q_1 p_1}{q_0 q_1} F(u, z) - \frac{q_0 p_1}{q_0 q_1} F(u-1, z)
\]

\[
- \frac{p}{q_0 q_1} \sum_{k=0}^{u} \phi(k) \bar{T}(u-k-1)
\]

\[
- \frac{p}{q_0 q_1} \left( \bar{T}(u-1) - \bar{T}(u+z-1) \right).
\]

(61)

By Theorem 7, we can obtain the asymptotic estimates of the distribution function of deficit at ruin. Consider

\[
F(u, z) \sim K_F(z) R^{-\nu},
\]

(62)
where

\[
K_F(z) = \left( [q_p_0 p_1 (R - 1) + p_0 q_R (R^x - 1)] \phi(0) \\
+ (R - 1) (q_p_0 p_1 - q_p_0 p_1 - p_1 p_1) \\
\times \sum_{m=1}^{x} R^m F (m - 1, z) + K_1 (R - 1) \right) \\
\times \left( (R - 1) \left( K_2 R + p \sum_{k=2}^{\infty} \tilde{T}(k - 2) \right) \right)^{-1},
\]

\[
K_1 = -p_0 q_1 K_3 - p_1 K_4 + K_5,
\]

\[
K_2 = q_p_0 p_1 + p_p_0 q_1 \tilde{P}(1) + p_q_0 p_1 + p (p_0 p_1 + q_0 q_1),
\]

\[
K_3 = \sum_{m=1}^{x} R^m \sum_{k=0}^{m-1} \tilde{T}(k) (\tilde{T}(k + z)),
\]

\[
K_4 = \sum_{m=1}^{x} R^m \sum_{k=0}^{m-2} \tilde{T}(k) (\tilde{T}(k + z)),
\]

\[
K_5 = \sum_{m=x+1}^{\infty} R^m (\tilde{T}(m - 1) - \tilde{T}(m + z - 1)).
\]

(63)

5.2. Numerical Illustration. The initial term \(\phi(0), \phi(1), \ldots, \phi(x)\) can be obtained by solving the set of linear equations (8) and (9). \(\phi(x + 1), \phi(x + 2), \ldots\) can be computed by two approaches, which are using the recursive formulas and asymptotic estimation, respectively. We will compare the asymptotic values for the ruin probability and distribution of the deficit at ruin with the exact values computed by the recursive formulas and analysis on the impact of the randomly paying dividends on the ruin probability and distribution of the deficit at ruin.

The numerical analysis will be performed using the following assumed parameters. The distribution of claim amount \(X_i\) is a zero-truncated geometric distribution with parameter \(\alpha = 9/10\), and then \(f(k) = (1 - 9/10)(9/10)^{i-1}, i = 1, 2, \ldots; p = 0.05\), and the threshold \(x = 5\). The four cases with the probability of paying dividend \(P = (p_0, p_1) = (0.9, 0.015), (0.75, 0.055)\) will be performed. The relative security loading are larger than zero in the four case, then there is a unique solution which is adjustment coefficient in each case. The adjustment coefficient \(R\) is computed and shown in Table 1.

The exact values calculated by recursive formulas (11)-(12) and the asymptotic values estimated by (42) are shown in Table 2 and Table 3 for the ruin probability and the distribution of the deficit at ruin, respectively. In both of the tables, the E.V means the exact value, and the A.V means the asymptotic value.

From Table 3, we can find that the asymptotic values of ruin probability are generally close to the exact values with the surplus \(u\) increasing under the cases \(P = (p_0, p_1) = (0.9, 0.015), (0.75, 0.015), (0.75, 0.055), (0.65, 0.055)\). It is easy to see that the ruin probability increases with decreasing probability of obtaining an insurance policy \(p_0\), and increases with raising the probability of paying dividend \(p_1\).

In Table 3, the exact values and asymptotic values for the distribution of the deficit at ruin when \(z = 10, 15\) are shown.
It suggests that the asymptotic values are more close to the exact values with the surplus increasing under the cases $P = (0.75, 0.015), (0.65, 0.055)$.

6. Conclusions

In order to describe the surplus of the nonlife insurance companies reasonably, the compound binomial risk model with randomly charging premiums and paying dividends to shareholders is proposed in this paper. Further, we derive the recursive formulas and asymptotic estimation of penalty function using classical method. The results about penalty function are applied to obtain the recursive formulas and asymptotic estimations of the ruin probability and the distribution of the deficit at ruin. The numerical examples show that the actual penalty function can be approached by asymptotic estimation. The results about the model are meaningful to analyze the ruin problem about the joint-stock nonlife insurance companies. It may provide the reference for decision-making of the joint-stock nonlife insurance companies about risk management.
