Review Article
A Philatelic Excursion with Jeff Hunter in Probability and Matrix Theory
George P. H. Styan and Götz Trenkler
Received 15 May 2007; Accepted 8 August 2007
Recommended by Paul Cowpertwait

We present an excursion with Jeff Hunter, visiting some of his research topics. Specifically, we will present some facts about certain people whose work seems to have influenced Jeff in his scientific career; we illustrate our presentation with postage stamps that have been issued in honour of these people. Our main guide is Hunter’s two-volume book entitled *Mathematical Techniques of Applied Probability* (Academic Press, 1983).

1. Introduction

In the following we are going on an excursion with Jeff Hunter, visiting some of his research topics. Specifically, we will present some facts about certain people whose work seems to have influenced Jeff in his scientific career. We illustrate our presentation with postage stamps that have been issued in honour of these people; we know that Jeff collects stamps. Our main guide will be the two-volume book [1, 2] by Hunter. (All but one of the postage stamps depicted in this article are identified with their Scott catalog numbers as found in the *Scott 2007 Standard Postage Stamp Catalogue* [3].)

2. Bernoulli, Seki, Leibniz and Chebyshev

One of the first entries of this two-volume treatment of applied probability is “Bernoulli trial” [1, page 10]: “... a sequence of independent trials is called a sequence of Bernoulli trials.” A Bernoulli trial is an experiment whose outcome is random and can be either “success” and “failure” [4].
The eldest of four brothers, Jacob Bernoulli I (also known as James Bernoulli; first name in German: Jakob, in French: Jacques) lived from 1654 to 1705, mainly in Switzerland. He is one of eight prominent mathematicians in the Bernoulli family [4] and is famous for his *Ars Conjectandi* [5] (published posthumously in 1713), a ground-breaking work on probability theory, and for his research concerning the law of large numbers, see Figure 2.1 (left panel).

The Bernoulli numbers \(B_k\) \((k = 0, 1, 2, \ldots)\) are a sequence of signed rational numbers that are implicitly defined by the identity

\[
\frac{x}{e^x - 1} = \sum_{k=0}^{\infty} \frac{B_k x^k}{k!}.
\]

Actually, the Japanese mathematician Takakazu Seki Kōwa (1642–1708) discovered these numbers before Jacob Bernoulli I. Seki also discovered determinants before Leibniz, see, for example, [6–8].

Gottfried Wilhelm von Leibniz (the surname “Leibniz” is sometimes written as “Leibnitz” [6]) (1646–1716) was a German polymath “of remarkable breadth of knowledge, who made original contributions to optics, mechanics, statistics, logic, and probability theory. He conceived the idea of calculating machines and of a universal language. He wrote on history, law, and political theory” [9]; see also [6].

The postage stamp from St. Vincent (in Figure 2.2) was issued for the “750th Anniversary of Hannover: Gottfried Wilhelm Leibniz. Head librarian for the electors of Hannover & co-inventor of calculus.”

The notion of “Markov chain” is already mentioned by Jeff Hunter in [1], but the main theory of Markov chains in discrete time is developed only in [2]. The early research of Andrey Andreyevich Markov (1856–1922) was much influenced by Pafnuty Lvovich Chebyshev (his surname is transliterated in various other ways, for example, Chebychev, Chebyshov, Tchebycheff, or Tschebyscheff [10, 11]) (1821–1894), see Figure 2.2 (right panel). Chebyshev is probably best known for his inequality, also known as...
Figure 2.2. (Left panel) Gottfried W. von Leibniz: St. Vincent 1991 (Scott 1557); (right panel) Pafnuty Lvovich Chebyshev: USSR 1946 (Scott 1051).

the Bienaymé-Chebyshev inequality:

\[ \Pr(\mid X - \mu \mid \geq k\sigma) \leq \frac{1}{k^2}, \]

(2.2)

where \( X \) has expected value \( \mu \) and variance \( \sigma^2 \), and \( k \) is any positive real number. We have not found a postage stamp that honours either Markov or the statistician Irenée–Jules Bienaymé (1796–1878), who proved (2.2) some years before Chebyshev, see, for example, Heyde and Seneta [12, page 132].

3. Wiener, Brownian Motion, Gauss, Laplace, Abel

Andrey Andreyevich Markov introduced the concept of a Markov chain as a working model for the study of dependent random variables. Brownian motion is a very good example of a continuous Markov process and is often called a Wiener process; Norbert Wiener (1894–1964) “was an American theoretical and applied mathematician, who is perhaps best known as the founder of cybernetics” [4].

Brownian motion, which is named after the botanist Robert Brown (1773–1858), “is either the random movement of particles suspended in a fluid or the mathematical model used to describe such random movements” [4].

A graph of Brownian motion is shown on a postage stamp (in Figure 3.1 (right panel) right-hand side, center) from Czechoslovakia. This stamp was issued in celebration of the 125th anniversary of the Union of Czechoslovakian Mathematicians and Physicists. Shown on the stamp is “geographical measurement from A. M. Malletta’s book (we have not been able to further identify this book), 1672, earth fold and Brownian motion diagrams” [3, volume 2, page 714].

We observe, however, that Jeff Hunter’s research interests focus mainly on discrete models. But even in discrete models, continuous distributions play a major role (see, e.g., volume 1, where the distribution of the number of recurrent events is shown to be
approximately normal). The normal distribution is attributed to Carl Friedrich Gauss (the surname “Gauss” is sometimes written as “Gauß”) (1777–1855).
Beyond mathematics, Gauss did research in astronomy, physics, and geodesy. His principal contributions to statistics are in the theory of least squares estimation, where major work was also done by the mathematician Pierre-Simon, Marquis de Laplace (1749–1827).

In connection with the behaviour of probability-generating functions and the application of discrete models, convergence problems of infinite series arise. In both volumes of his book, Jeff has to apply Abel’s convergence theorem to solve these problems. Niels Henrik Abel (1802–1829) was a Norwegian mathematician, who is best known for proving the impossibility of finding, in closed form, the roots of a polynomial of degree greater than 4. Beyond group theory (“Abelian group”), Abel was especially interested in the theory of functions. In 2001 the government of Norway announced that the bicentennial of Abel’s birth (1802) would mark the commencement of a new prize for mathematicians, named after Abel. The Abel Prize is similar to the Nobel Prize which is awarded in Sweden and Norway, but excludes mathematics. Sathamangalam R. Srinivasa Varadhan (born 1940) received the 2007 Abel Prize for his fundamental contributions to probability theory [4].

4. Euler, Banachiewicz, Penrose triangle, and Hawking

Matrix theory is a powerful tool which has been widely used by Jeff Hunter in his research papers to further the understanding of the main features of Markov chains. Jeff also devoted one chapter of his book to these techniques. Although Leonhard Euler (1707–1783) did not explicitly use the notion of a matrix (explicitly created only in the mid-19th century), in 1776 Euler created several magic squares, including a $4 \times 4$ magic square [13, page 8], [14, 15] which may be represented by the matrix

\[
M = \begin{pmatrix}
8 & 10 & 15 & 1 \\
11 & 5 & 4 & 14 \\
2 & 16 & 9 & 7 \\
13 & 3 & 6 & 12
\end{pmatrix}.
\] (4.1)

Dividing each element of $M$ by 34 yields a doubly stochastic matrix [1, page 127].

When inverting large-scale matrices, Jeff applies results from the theory of partitioned matrices. The latter notion can be traced back to Tadeusz Banachiewicz (1882–1954), who was a Polish astronomer, mathematician, and geodesist, see, for example, [8, 16].

The Banachiewicz inversion formula can be stated as

\[
\begin{pmatrix}
P & Q \\
R & S
\end{pmatrix}^{-1} = \begin{pmatrix}
P^{-1} + P^{-1}Q T^{-1} R P^{-1} & -P^{-1} Q T^{-1} \\
-T^{-1} R P^{-1} & T^{-1}
\end{pmatrix},
\] (4.2)

where $T = S - R P^{-1} Q$. The matrix $T$ is known as a Schur complement, a concept that has become increasingly important in statistics and applied mathematics in recent years, see, for example, Zhang [17]. In 1925, Banachiewicz invented a theory of “cracovians” (Cracovian calculus), a special kind of matrix algebra, which brought him international recognition. This theory solved several astronomical, geodesic, mechanical, and mathematical problems [4].
Jeff Hunter has participated in numerous conferences and workshops dedicated to matrix theory and probability, and related fields. In some of these meetings he met the statistician Calyampudi Radhakrishna Rao (born 1920), where both were invited speakers. Rao’s tool of a generalized inverse of a matrix was one of Jeff’s favourites (see [2] and his research papers, e.g., [18, 19]). (Calyampudi Radhakrishna Rao was the Ph.D. thesis adviser for the 2007 Abel Prize laureate Sathamangalam R. Srinivasa Varadhan, see Section 3.) As is well known, every matrix has a generalized inverse which, however, need not be unique. The Moore-Penrose inverse of a complex matrix $A$ is, however, the unique matrix $G$ satisfying the four equations

$$AGA = A, \quad GAG = G, \quad AG = (AG)^*, \quad GA = (GA)^*,$$

(4.3)

where the superscript $*$ denotes conjugate transpose. See, for example, [20, page 40].
The Moore-Penrose inverse is named after the mathematician Eliakim Hastings Moore (1862–1932) and the renowned mathematical physicist Sir Roger Penrose (born 1931). It should be mentioned that Penrose, after his research on generalized inverses of matrices in the 1950s, apparently did not pursue his matrix interests any further, but started to work on singularities in the framework of general relativity, together with the famous theoretical physicist Stephen William Hawking (born 1942). The Penrose triangle (Figure 4.2, left panel) is an impossible object first created by the Swedish artist Oscar Reutersvård (1915–2002) in 1934. Sir Roger Penrose independently devised and popularised it in the 1950s, describing it as “impossibility in its purest form.”

5. Poincaré, Gödel, Kolmogorov, Carroll, and Hua

Jules Henri Poincaré (1854–1912) “was one of France’s greatest mathematicians and theoretical physicists, and a philosopher of science” [4] and in 1886 he was appointed to the Chair of Mathematical Physics and Probability at the Sorbonne. Poincaré is famous for geometric probability. In matrix theory there is the Poincaré separation theorem for eigenvalues, see, for example, [21]:

\[
\begin{align*}
\text{ch}_{n-p+i}(A) &\leq \text{ch}_i(F'AF) \leq \text{ch}_i(A), & i = 1, \ldots, p \leq n, \\
\end{align*}
\]

where \(\text{ch}_i\) denotes the \(i\)th largest eigenvalue. Here the matrix \(A\) is a real symmetric \(n \times n\) matrix and \(F\) is a real \(n \times p\) matrix such that \(F'F = FF' = I_p\), the \(p \times p\) identity matrix and \(F'\) is the transpose of \(F\).

The postage stamp shown in Figure 5.1 was issued by Portugal as part of a large set in celebration of the 20th century, and includes Kurt Gödel (1906–1978) in addition to Poincaré and Andrey Nikolaevich Kolmogorov (1903–1987).

Kurt Gödel was a mathematician and philosopher. “One of the most significant logicians of all time, Gödel’s work has had an immense impact upon scientific and philosophical thinking in the 20th century” [4].

Andrey Nikolaevich Kolmogorov, who is widely considered one of the prominent mathematicians of the 20th century, made major advances in probability theory (as well
as topology, intuitionistic logic, turbulence, classical mechanics, and computational complexity). Kolmogorov observed that “The theory of probability as a mathematical discipline can and should be developed from axioms in exactly the same way as geometry and algebra” [4].

In connection with matrices, the notion of determinant is indispensable. We have already mentioned that Seki invented determinants a few years before Leibniz. Jeff’s book contains a nice collection of rules for determinants.

The first books solely dedicated to determinants, see, for example, [22], were written by the mathematician and physicist William Spottiswoode (1825–1883) and by the author, mathematician, Anglican clergyman, and photographer Rev. Charles Lutwidge Dodgson (1832–1908), who is better known as Lewis Carroll [23]; his books [24, 25] entitled Condensation of Determinants [24] and An Elementary Treatise on Determinants [25] are far less well known than his famous Alice’s Adventures in Wonderland (1865) and its sequel Through the Looking-Glass, and What Alice Found There (1871), recently reissued (with an introduction by Martin Gardner) as a single paperback [26]. (The 6-page booklet Condensation of Determinants [24] is just a reprint of an article published in the Proceedings of the Royal Society of London but An Elementary Treatise on Determinants [25] is a 143-page book published by Macmillan, London, 1867.)

Loo-Keng Hua (1910–1985) was a great mathematician and a Chinese legendary hero. (The name “Loo-Keng Hua” is also written as “Hua Loo-keng” [27].) He had little formal education, but made enormous contributions to number theory, algebra, complex analysis, matrix geometry, and applied mathematics” [28, 29]. In particular the inequality

$$\det(I - A^*A) \cdot \det(I - B*B) \leq |\det(I - A^*B)|^2$$

(5.2)

is known as the “Hua determinantal inequality” [18, 30, 21]. Here the matrices $A$ and $B$ are contractive, that is, the singular values all lie in the half-open unit interval $[0,1)$; on the right-hand side of (5.2), the symbol $|\cdot|$ denotes absolute value.

We conclude this little excursion into the world of stamps and mathematics by expressing again our appreciation for Jeff’s outstanding research activities, especially in matrix theory. We are sure that his retirement will be the starting point for new adventures in this attractive field.

Go ahead, Jeff!
Acknowledgments

The authors are most grateful to three anonymous referees for their helpful comments. Many of the images of stamps have been taken, with permission, from the excellent website of Jeff Miller [31]; see also the Reinhardt website [32] and the beautiful book by Robin Wilson [33]. For biographical material the authors consulted Abbott [34], Crystal [9], Heyde and Seneta [12], Johnson and Kotz [35], and Meyer [35], as well as the excellent open-access websites of MacTutor [11] and Wikipedia [4]. For closely related material, please see [8]. Many thanks to Evelyn Matheson Styan for her help; she also joins the authors in wishing Jeff a very happy retirement. This research has been supported in part by the Natural Sciences and Engineering Research Council of Canada.
