# A geometrical meaning of the Riemann tensor: parallel transport around a closed loop. ${ }^{1}$ 

6 November 2002

In flat space, if you parallel transport a vector around a closed loop it always comes back to itself. This isn't true in curved space, the purpose of this calculation it to show that the change in a vector after it is transported around a closed loop is related to the Riemann tensor. The calculation is done for a small loop begining and ending at a point $p$ and we find that the leading order change to the vector depends on the Riemann cuvature at $p$. The calcuation would be much more difficult for a loop that wasn't small, the change would involve integrating a complicated function around the loop. By taking the loop to be small we can expand all our quantities around their value at $p$.

So, consider a point $p$ with coördinates $X^{a}$. Let

$$
\begin{equation*}
x^{a}(t)=X^{a}+\epsilon z^{t} \tag{1}
\end{equation*}
$$

with $\epsilon \ll 1$ and $z^{a}(0)=z^{a}(T)=0$ be a small loop begining and ending at $p$. If $V^{a}$ is a vector at $p$ then the parallel transported vector $V^{a}(t)$ satisfies the parallel transport equation

$$
\begin{equation*}
U^{a} \nabla_{a} V^{b}(t)=0 \tag{2}
\end{equation*}
$$

with, as usual,

$$
\begin{equation*}
U^{a}=\frac{d x^{a}}{d t} \tag{3}
\end{equation*}
$$

and $V^{a}(0)=V^{a}$. From now on we will use quantities without an arguement to mean the same quantity at the start of the loop at $p$, that is with $t=0$.

Writing the parallel transport equation (??) out more explicitly

$$
\begin{equation*}
\frac{d V^{a}(t)}{d t}+\Gamma_{b c}^{a}(t) U^{b}(t) V^{c}(t)=0 \tag{4}
\end{equation*}
$$

where these quantities all depend on $t$ through their spatial dependence. This can be integrated to give

$$
\begin{equation*}
V^{a}(t)-V^{a}=-\int_{0}^{t} d t^{\prime} \Gamma^{a} b c\left(t^{\prime}\right) U^{b}\left(t^{\prime}\right) V^{c}\left(t^{\prime}\right) \tag{5}
\end{equation*}
$$

[^0]Furthermore, we know

$$
\begin{equation*}
U^{b}(t)=\epsilon \frac{d z^{b}(t)}{d t} \tag{6}
\end{equation*}
$$

This means that the integrand in (??) is order $\epsilon$, and, if we want the leading order expression for $V^{a}(t)$ we only need the zeroth order expressions for $\Gamma_{b c}^{a}\left(t^{\prime}\right)$ and $V^{c}\left(t^{\prime}\right)$ in the integrand. In other words, by Taylor expansion

$$
\begin{align*}
\Gamma_{b c}^{a}\left(t^{\prime}\right) & =\Gamma_{b c}^{a}+O(\epsilon) \\
V^{a}\left(t^{\prime}\right) & =V^{a}+O(\epsilon) . \tag{7}
\end{align*}
$$

Putting this into the equation gives

$$
\begin{equation*}
V^{a}(t)-V^{a}=-\epsilon \Gamma^{a} b c V^{c} \int_{0}^{t} d t^{\prime} \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}}=-\epsilon \Gamma^{a} b c V^{c} z^{b}(t)+O\left(\epsilon^{2}\right) \tag{8}
\end{equation*}
$$

Hence, using $z^{b}(T)=0$

$$
\begin{equation*}
V^{a}(T)=V^{a}+O\left(\epsilon^{2}\right) \tag{9}
\end{equation*}
$$

This means that the vector is the same after to parallel transport, to the second order in $\epsilon$.

We now calculate the next order in $\epsilon$. We can do this because we have now worked out $V^{a}(t)$ to first order. Hence, by Taylor expansion

$$
\begin{equation*}
\Gamma_{b c}^{a}\left(t^{\prime}\right)=\Gamma_{b c}^{a}+\epsilon z^{d} \Gamma_{b c, d}^{a}+O\left(\epsilon^{2}\right) \tag{10}
\end{equation*}
$$

and, by the above

$$
\begin{equation*}
V^{a}\left(t^{\prime}\right)=V^{a}-\epsilon \Gamma^{a} b c V^{c} \int_{0}^{t} d t^{\prime} \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}}=-\epsilon \Gamma^{a} b c V^{c} z^{b}\left(t^{\prime}\right)+O\left(\epsilon^{2}\right) \tag{11}
\end{equation*}
$$

Substituting this into the equation for $V^{a}(t)(? ?)$ we get

$$
\begin{equation*}
V^{a}(t)-V^{a}=-\epsilon \int_{0}^{t} d t^{\prime}\left[\Gamma_{b c}^{a}+\epsilon \Gamma_{b c, d}^{a} z^{d}(t)\right] \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}}\left[V^{c}-\epsilon \Gamma_{e f}^{c} V^{e} z^{f}(t)\right]+O\left(\epsilon^{3}\right) \tag{12}
\end{equation*}
$$

If we evaluate at $t=T$ the order $\epsilon$ part vanishes and we get

$$
\begin{align*}
V^{a}(T)-V^{a} & =\epsilon^{2} \int_{0}^{t} d t^{\prime}\left[\Gamma_{b c}^{a} \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}} \Gamma_{e f}^{c} V^{e} z^{f}(t)-\Gamma_{b c, d}^{a} z^{d}(t) \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}} V^{c}\right]+O\left(\epsilon^{3}\right) \\
& =\epsilon^{2}\left[\Gamma_{b e}^{a} \Gamma_{c d}^{e}-\Gamma_{b c, d}^{a}\right] V^{c} \int_{0}^{t} d t^{\prime} \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}} z^{d}\left(t^{\prime}\right)+O\left(\epsilon^{3}\right) \tag{13}
\end{align*}
$$

where, for convenience, we have renamed some of the summed indices. Next, we use integration by parts and the boundary conditions $z^{a}(0)=z^{a}(T)=0$ to show

$$
\begin{equation*}
\int_{0}^{t} d t^{\prime} \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}} z^{d}\left(t^{\prime}\right)=-\int_{0}^{t} d t^{\prime} \frac{d z^{d}\left(t^{\prime}\right)}{d t^{\prime}} z^{b}\left(t^{\prime}\right) \tag{14}
\end{equation*}
$$

This allows us to antisymmetrize the indices $b$ and $d$ in the expression for $V^{a}(T)-V^{a}(? ?)$ :

$$
\begin{equation*}
V^{a}(T)-V^{a}=\epsilon^{2} \frac{1}{2}\left[\Gamma_{b e}^{a} \Gamma_{c d}^{e}-\Gamma_{d e}^{a} \Gamma_{c b}^{e}-\Gamma_{b c, d}^{a}+\Gamma_{d c, b}^{a}\right] V^{c} \int_{0}^{t} d t^{\prime} \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}} z^{d}\left(t^{\prime}\right)+O\left(\epsilon^{3}\right) \tag{15}
\end{equation*}
$$

Now, we know

$$
\begin{equation*}
R_{a b c}^{d}=\Gamma_{a c, b}^{d}-\Gamma_{b c, a}^{d}+\Gamma_{a c}^{f} \Gamma_{b f}^{d}-\Gamma_{b c}^{f} \Gamma_{a f}^{d}+O\left(\epsilon^{3}\right) \tag{16}
\end{equation*}
$$

so, with zero torsion,

$$
\begin{equation*}
V^{a}(T)-V^{a}=\epsilon^{2} \frac{1}{2} R_{d c b}{ }^{a} V^{c} \int_{0}^{t} d t^{\prime} \frac{d z^{b}\left(t^{\prime}\right)}{d t^{\prime}} z^{d}\left(t^{\prime}\right) \tag{17}
\end{equation*}
$$

Thus, to leading order the change in the vector depends on the Riemann tensor at $p$ and on an integral factor which does not depend on the derivative of the metric. The integral factor is related to the size of the loop; it is easy to see that it is the area of the loop if the loop is a parallelogram.

Don't worry too much about which of the indices of the Riemann tensor is raised, this can always be moved around using the symmetries of the Riemann tensor:

$$
\begin{equation*}
R_{d c b}{ }^{a}=g^{a e} R_{d c b e}=g^{a e} R_{b e d c}=g^{a e} R_{e b c d}=R_{b c d}^{a} \tag{18}
\end{equation*}
$$
