MAU23203—Analysis in Several Variables School of Mathematics, Trinity College Michaelmas Term 2022 Section 10: Second Order Partial Derivatives and the Hessian Matrix

Trinity College Dublin

## 9.1. Second Order Partial Derivatives

Let X be an open subset of  $\mathbb{R}^n$  and let  $f: X \to \mathbb{R}$  be a real-valued function on X. We consider the second order partial derivatives of the function f defined by

$$\frac{\partial^2 f}{\partial x_i \, \partial x_j} = \frac{\partial}{\partial x_i} \left( \frac{\partial f}{\partial x_j} \right).$$

We shall show that if the partial derivatives

$$\frac{\partial f}{\partial x_i}, \quad \frac{\partial f}{\partial x_j}, \quad \frac{\partial^2 f}{\partial x_i \partial x_j} \text{ and } \frac{\partial^2 f}{\partial x_j \partial x_i}$$

all exist and are continuous then

$$\frac{\partial^2 f}{\partial x_i \, \partial x_j} = \frac{\partial^2 f}{\partial x_j \, \partial x_i}.$$

Now it would be incorrect to assert that if the second order partial derivatives of a real-valued function f of real variables  $x_1, x_2, \ldots, x_n$  all exist at some point of the domain of the function then

$$\frac{\partial^2 f}{\partial x_i \, \partial x_j}$$
 and  $\frac{\partial^2 f}{\partial x_j \, \partial x_i}$ .

are equal for all values of i and j.

First though we give a counterexample which demonstrates that there exist functions f for which

$$\frac{\partial^2 f}{\partial x_i \partial x_j} \neq \frac{\partial^2 f}{\partial x_j \partial x_i}.$$

#### Example

Let  $f: \mathbb{R}^2 \to \mathbb{R}$  be the function defined by

$$f(x,y) = \begin{cases} \frac{xy(x^2 - y^2)}{x^2 + y^2} & \text{if } (x,y) \neq (0,0); \\ 0 & \text{if } (x,y) = (0,0). \end{cases}$$

For convenience of notation, let us write

$$f_{x}(x,y) = \frac{\partial f(x,y)}{\partial x},$$
  

$$f_{y}(x,y) = \frac{\partial f(x,y)}{\partial y},$$
  

$$f_{xy}(x,y) = \frac{\partial^{2} f(x,y)}{\partial x \partial y},$$
  

$$f_{yx}(x,y) = \frac{\partial^{2} f(x,y)}{\partial y \partial x}.$$

If  $(x, y) \neq (0, 0)$  then

$$f_{x} = \frac{(3x^{2}y - y^{3})(x^{2} + y^{2}) - 2x^{2}y(x^{2} - y^{2})}{(x^{2} + y^{2})^{2}}$$
  
=  $\frac{3x^{4}y + 3x^{2}y^{3} - x^{2}y^{3} - y^{5} - 2x^{4}y + 2x^{2}y^{3}}{(x^{2} + y^{2})^{2}}$   
=  $\frac{x^{4}y + 4x^{2}y^{3} - y^{5}}{(x^{2} + y^{2})^{2}}.$ 

Similarly

$$f_y = rac{-xy^4 - 4x^3y^2 + x^5}{(x^2 + y^2)^2}.$$

(This can be deduced from the formula for  $f_x$  on noticing that f(x, y) changes sign on interchanging the variables x and y.)

Differentiating again, when  $(x, y) \neq (0, 0)$ , we find that

$$f_{xy}(x,y) = \frac{\partial f_y}{\partial x}$$

$$= \frac{(-y^4 - 12x^2y^2 + 5x^4)(x^2 + y^2)}{(x^2 + y^2)^3}$$

$$+ \frac{-4x(-xy^4 - 4x^3y^2 + x^5)}{(x^2 + y^2)^3}$$

$$= \frac{-x^2y^4 - 12x^4y^2 + 5x^6 - y^6 - 12x^2y^4 + 5x^4y^2}{(x^2 + y^2)^3}$$

$$+ \frac{4x^2y^4 + 16x^4y^2 - 4x^6}{(x^2 + y^2)^3}$$

$$= \frac{x^6 + 9x^4y^2 - 9x^2y^4 - y^6}{(x^2 + y^2)^3}.$$

#### 9. Second Order Partial Derivatives and the Hessian Matrix (continued)

Now the expression just obtained for  $f_{xy}$  when  $(x, y) \neq (0, 0)$  changes sign when the variables x and y are interchanged. The same is true of the expression defining f(x, y). It follows that  $f_{yx}$ . We conclude therefore that if  $(x, y) \neq (0, 0)$  then

$$f_{xy} = f_{yx} = \frac{x^6 + 9x^4y^2 - 9x^2y^4 - y^6}{(x^2 + y^2)^3}.$$

Now if  $(x, y) \neq (0, 0)$  and if  $r = \sqrt{x^2 + y^2}$  then

$$|f_x(x,y)| = \frac{|x^4y + 4x^2y^3 - y^5|}{r^4} \le \frac{6r^5}{r^4} = 6r.$$

It follows that

$$\lim_{(x,y)\to(0,0)}f_x(x,y)=0.$$

Similarly

$$\lim_{(x,y)\to(0,0)}f_y(x,y)=0.$$

However

$$\lim_{(x,y)\to(0,0)}f_{xy}(x,y)$$

does not exist. Indeed

$$\lim_{x \to 0} f_{xy}(x,0) = \lim_{x \to 0} f_{yx}(x,0) = \lim_{x \to 0} \frac{x^6}{x^6} = 1,$$
$$\lim_{y \to 0} f_{xy}(0,y) = \lim_{y \to 0} f_{yx}(0,y) = \lim_{y \to 0} \frac{-y^6}{y^6} = -1.$$

Next we show that  $f_x$ ,  $f_y$ ,  $f_{xy}$  and  $f_{yx}$  all exist at (0,0), and thus exist everywhere on  $\mathbb{R}^2$ . Now f(x,0) = 0 for all x, hence  $f_x(0,0) = 0$ . Also f(0,y) = 0 for all y, hence  $f_y(0,0) = 0$ . Thus

$$f_y(x,0) = x, \qquad f_x(0,y) = -y$$

for all  $x, y \in \mathbb{R}$ .

We conclude that

$$\begin{aligned} f_{xy}(0,0) &= \left. \frac{d(f_y(x,0))}{dx} \right|_{x=0} = 1, \\ f_{yx}(0,0) &= \left. \frac{d(f_x(0,y))}{dy} \right|_{y=0} = -1, \end{aligned}$$

#### Thus

$$\frac{\partial^2 f}{\partial x \partial y} \neq \frac{\partial^2 f}{\partial y \partial x}$$

at (0,0). Observe that in this example the functions  $f_{xy}$  and  $f_{yx}$  are continuous throughout  $\mathbb{R}^2 \setminus \{(0,0)\}$  and are equal to one another there. Although the functions  $f_{xy}$  and  $f_{yx}$  are well-defined at (0,0), they are not continuous at (0,0) and  $f_{xy}(0,0) \neq f_{yx}(0,0)$ .

#### Theorem 9.1

Let X be an open set in  $\mathbb{R}^2$  and let  $f : X \to \mathbb{R}$  be a real-valued function on X. Suppose that the partial derivatives

$$\frac{\partial f}{\partial x}, \quad \frac{\partial f}{\partial y} \quad \text{and} \quad \frac{\partial^2 f}{\partial x \partial y}$$

exist and are continuous throughout X. Then the partial derivative

 $\frac{\partial^2 f}{\partial y \partial x}$ 

exists and is continuous on X, and

$$\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial^2 f}{\partial y \partial x}.$$

# Proof

Let

$$f_{x}(x,y) = \frac{\partial f}{\partial x}, \quad f_{y}(x,y) = \frac{\partial f}{\partial y},$$
$$f_{xy}(x,y) = \frac{\partial^{2} f}{\partial x \partial y} \text{ and } f_{yx}(x,y) = \frac{\partial^{2} f}{\partial y \partial x}$$

and let (a, b) be a point of X. The set X is open in  $\mathbb{R}^2$  and therefore there exists some positive real number L such that  $(a+h, b+k) \in X$  for all  $(h, k) \in \mathbb{R}^2$  satisfying |h| < L and |k| < L.

Let

$$S(h,k) = f(a+h,b+k) + f(a,b) - f(a+h,b) - f(a,b+k)$$

for all real numbers *h* and *k* satisfying |h| < L and |k| < L. First consider *h* to be fixed, where |h| < L, and let  $q: (b-L, b+L) \rightarrow \mathbb{R}$  be defined so that q(t) = f(a+h,t) - f(a,t) for all real numbers *t* satisfying b - L < t < b + L. Then S(h,k) = q(b+k) - q(b). It then follows from the Mean Value Theorem (Theorem 7.5) that there exists some real number *v* lying between *b* and b + k for which q(b+k) - q(b) = kq'(v). But  $q'(v) = f_y(a+h,v) - f_y(a,v)$ . It follows that

$$S(h,k) = k(f_y(a+h,v) - f_y(a,v)).$$

The Mean Value Theorem can now be applied to the function sending real numbers *s* in the interval (a - L, a + L) to  $f_y(s, v)$  to deduce the existence of a real number *u* lying between *a* and *a* + *h* for which

$$S(h,k) = k(f_y(a+h,v) - f_y(a,v))$$
  
=  $hkf_{xy}(u,v)$   
=  $hk \frac{\partial^2 f}{\partial x \partial y}\Big|_{(x,y)=(u,v)}$ .

Now let some positive real number  $\varepsilon$  be given. The function  $f_{xy}$  is continuous. Therefore there exists some real number  $\delta$  satisfying  $0 < \delta < L$  such that  $|f_{xy}(a+h, b+k) - f_{xy}(a, b)| \le \varepsilon$  whenever  $|h| < \delta$  and  $|k| < \delta$ . It follows that

$$\left|\frac{S(h,k)}{hk} - f_{xy}(a,b)\right| \leq \varepsilon$$

for all real numbers h and k satisfying  $0 < |h| < \delta$  and  $0 < |k| < \delta.$  Now

$$\lim_{h \to 0} \frac{S(h,k)}{hk} = \frac{1}{k} \lim_{h \to 0} \frac{f(a+h,b+k) - f(a,b+k)}{h}$$
$$-\frac{1}{k} \lim_{h \to 0} \frac{f(a+h,b) - f(a,b)}{h}$$
$$= \frac{f_x(a,b+k) - f_x(a,b)}{k}.$$

## It follows that

$$\frac{f_x(a,b+k)-f_x(a,b)}{k}-f_{xy}(a,b)\Big|\leq \varepsilon$$

whenever  $0 < |k| < \delta$ .

Thus the difference quotient  $\frac{f_x(a, b+k) - f_x(a, b)}{k}$  tends to  $f_{xy}(a, b)$  as k tends to zero, and therefore the second order partial derivative  $f_{yx}$  exists at the point (a, b) and

$$f_{yx}(a,b) = \lim_{k \to 0} \frac{f_x(a,b+k) - f_x(a,b)}{k} = f_{xy}(a,b)$$

as required.

## Corollary 9.2

Let X be an open set in  $\mathbb{R}^n$  and let  $f: X \to \mathbb{R}$  be a real-valued function on X. Suppose that the partial derivatives

 $\frac{\partial f}{\partial x_i}$  and  $\frac{\partial^2 f}{\partial x_i \partial x_j}$ 

exist and are continuous on X for all integers i and j between 1 and n. Then

 $\frac{\partial^2 f}{\partial x_i \partial x_j} = \frac{\partial^2 f}{\partial x_j \partial x_i}$ 

for all integers i and j between 1 and n.

# 9.2. Local Maxima and Minima

## Definition

A function  $\varphi: X \to \mathbb{R}^p$ , defined over an open set X in  $\mathbb{R}^n$  and mapping that open set into  $\mathbb{R}^p$  for some positive integers n and p, is said to be k times continuously differentiable if the partial derivatives of the components of the functions  $\varphi$  of all orders less than or equal to k exist and are continuous throughout the domain X of the function  $\varphi$ . Let  $f: X \to \mathbb{R}$  be a twice continuously differentiable real-valued function defined over some open subset X of  $\mathbb{R}^n$ . (In other words, let f be a real-valued function defined on an open set X in  $\mathbb{R}^n$ whose first and second order partial derivatives exist and are continuous throughout the domain X of the function f.) Suppose that f has a local minimum at some point **p** of X, where  $\mathbf{p} = (p_1, p_2, \dots, p_n)$ . Now for each integer *i* between 1 and *n* the map

$$t\mapsto f(p_1,\ldots,p_{i-1},t,p_{i+1},\ldots,p_n)$$

has a local minimum at  $t = p_i$ . It follows that the derivative of this map vanishes there. Thus if f has a local minimum at  $\mathbf{p}$  then

$$\left.\frac{\partial f}{\partial x_i}\right|_{\mathbf{x}=\mathbf{p}}=0.$$

In many situations the values of the second order partial derivatives of a twice continuously differentiable function of several real variables at a stationary point determines the qualitative behaviour of the function around that stationary point, in particular ensuring, in some situations, that the stationary point is a local minimum or a local maximum.

## **Proposition 9.3**

Let f be a twice continuously differentiable real-valued function defined over an open ball in  $\mathbb{R}^n$  of radius  $\delta$  centred on some point **p** of  $\mathbb{R}^n$ . Then, given any vector **h** in  $\mathbb{R}^n$  satisfying  $|\mathbf{h}| < \delta$ , there exists some real number  $\theta$  satisfying  $0 < \theta < 1$  for which

$$f(\mathbf{p}+\mathbf{h}) = f(\mathbf{p}) + \sum_{k=1}^{n} h_k \left. \frac{\partial f}{\partial x_k} \right|_{\mathbf{p}} + \frac{1}{2} \sum_{j,k=1}^{n} h_j h_k \left. \frac{\partial^2 f}{\partial x_j \partial x_k} \right|_{\mathbf{p}+\theta\mathbf{h}}.$$

## Proof

Let **h** satisfy  $|\mathbf{h}| < \delta$ , and let  $q(t) = f(\mathbf{p} + t\mathbf{h})$  for all real numbers t in some appropriately chosen open interval in the real line that contains the real numbers 0 and 1.

#### 9. Second Order Partial Derivatives and the Hessian Matrix (continued)

The function q is the composition function in which the function f follows the function that sends real numbers t in the domain of q to the point  $\mathbf{p} + t\mathbf{h}$  of  $\mathbb{R}^n$ . It follows, on applying the Chain Rule for differentiable functions of several real variables (Theorem 8.20) that

$$q'(t) = \sum_{k=1}^n h_k(\partial_k f)(\mathbf{p} + t\mathbf{h})$$

and

$$q''(t) = \sum_{j,k=1}^n h_j h_k (\partial_j \partial_k f) (\mathbf{p} + t\mathbf{h}),$$

where

$$(\partial_j f)(x_1, x_2, \ldots, x_n) = \frac{\partial f(x_1, x_2, \ldots, x_n)}{\partial x_j}$$

and

$$(\partial_j \partial_k f)(x_1, x_2, \ldots, x_n) = \frac{\partial^2 f(x_1, x_2, \ldots, x_n)}{\partial x_j \partial x_k}$$

Now

$$q(1) = q(0) + q'(0) + \frac{1}{2}q''(\theta)$$

for some real number  $\theta$  satisfying  $0 < \theta < 1$  (see Proposition 7.10). Consequently

$$f(\mathbf{p} + \mathbf{h}) = f(\mathbf{p}) + \sum_{k=1}^{n} h_{k}(\partial_{k}f)(\mathbf{p}) + \frac{1}{2} \sum_{j,k=1}^{n} h_{j}h_{k}(\partial_{j}\partial_{k}f)(\mathbf{p} + \theta\mathbf{h}) = f(\mathbf{p}) + \sum_{k=1}^{n} h_{k} \left. \frac{\partial f}{\partial x_{k}} \right|_{\mathbf{p}} + \frac{1}{2} \sum_{j,k=1}^{n} h_{j}h_{k} \left. \frac{\partial^{2}f}{\partial x_{j} \partial x_{k}} \right|_{\mathbf{p} + \theta\mathbf{h}},$$

as required.

Let f be a twice continuously differentiable real-valued function defined over an open ball of radius  $\delta$  about some given point **p** of  $\mathbb{R}^n$ . It follows from Proposition 9.3 that if

$$\left. \frac{\partial f}{\partial x_j} \right|_{\mathbf{p}} = 0$$

for j = 1, 2, ..., n, and if  $|\mathbf{h}| < \delta$  then there exists some real number  $\theta$  satisfying  $0 < \theta < 1$  for which

$$f(\mathbf{p} + \mathbf{h}) = f(\mathbf{p}) + \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} h_{i} h_{j} \left. \frac{\partial^{2} f}{\partial x_{i} \partial x_{j}} \right|_{\mathbf{x} = \mathbf{p} + \theta \mathbf{h}}$$

Let f be a real-valued function defined over an open set in  $\mathbb{R}^n$  whose second order partial derivative are defined at a point  $\mathbf{p}$  of its domain. Let us denote by  $(H_{i,j}(\mathbf{p}))$  the *Hessian matrix* at the point  $\mathbf{p}$ , defined by

$$H_{i,j}(\mathbf{p}) = \left. \frac{\partial^2 f}{\partial x_i \partial x_j} \right|_{\mathbf{x}=\mathbf{p}}$$

Suppose now that the function f is twice continuously differentiable on its domain. Then  $H_{i,j}(\mathbf{p}) = H_{j,i}(\mathbf{p})$  for all integers i and j between 1 and n, by Corollary 9.2, and thus the Hessian matrix is symmetric.

We now recall some facts concerning symmetric matrices.

Let  $(c_{i,i})$  be a symmetric  $n \times n$  matrix.

The matrix  $(c_{i,j})$  is said to be *positive semi-definite* if  $\sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j}h_ih_j \ge 0 \text{ for all } (h_1, h_2, \dots, h_n) \in \mathbb{R}^n.$ 

The matrix  $(c_{i,j})$  is said to be *positive definite* if  $\sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j}h_{i}h_{j} > 0 \text{ for all non-zero } (h_{1}, h_{2}, \dots, h_{n}) \in \mathbb{R}^{n}.$ 

The matrix  $(c_{i,j})$  is said to be *negative semi-definite* if  $\sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j} h_i h_j \leq 0 \text{ for all } (h_1, h_2, \dots, h_n) \in \mathbb{R}^n.$ 

The matrix 
$$(c_{i,j})$$
 is said to be *negative definite* if  

$$\sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j} h_i h_j < 0 \text{ for all non-zero } (h_1, h_2, \dots, h_n) \in \mathbb{R}^n.$$

The matrix  $(c_{i,j})$  is said to be *indefinite* if it is neither positive semi-definite nor negative semi-definite.

#### Lemma 9.4

Let  $(c_{i,j})$  be a positive definite symmetric  $n \times n$  matrix. Then there exists some positive real number  $\varepsilon$  that is small enough to ensure that any symmetric  $n \times n$  matrix  $(b_{i,j})$  whose components all satisfy the inequality  $|b_{i,j} - c_{i,j}| < \varepsilon$  is positive definite.

# **Proof** Let $S^{n-1}$ be the unit (n-1)-sphere in $\mathbb{R}^n$ defined by

$$S^{n-1} = \{(h_1, h_2, \ldots, h_n) \in \mathbb{R}^n : h_1^2 + h_2^2 + \cdots + h_n^2 = 1\}.$$

Observe that a symmetric  $n \times n$  matrix  $(b_{i,j})$  is positive definite if and only if

$$\sum_{i=1}^n \sum_{j=1}^n b_{i,j} h_i h_j > 0$$

for all  $(h_1, h_2, \ldots, h_n) \in S^{n-1}$ . Now the matrix  $(c_{i,j})$  is positive definite, by assumption. Therefore

$$\sum_{i=1}^n \sum_{j=1}^n c_{i,j} h_i h_j > 0$$

for all  $(h_1, h_2, ..., h_n) \in S^{n-1}$ .

But  $S^{n-1}$  is a closed bounded set in  $\mathbb{R}^n$ , it therefore follows from Theorem 5.10 that there exists some  $(k_1, k_2, \ldots, k_n) \in S^{n-1}$  with the property that

$$\sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j} h_i h_j \ge \sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j} k_i k_j$$

for all  $(h_1, h_2, \ldots, h_n) \in S^{n-1}$ . Let

$$A = \sum_{i=1}^n \sum_{j=1}^n c_{i,j} k_i k_j.$$

Then A > 0 and

$$\sum_{i=1}^n \sum_{j=1}^n c_{i,j} h_i h_j \ge A$$

for all  $(h_1, h_2, \ldots, h_n) \in S^{n-1}$ . Set  $\varepsilon = A/n^2$ .

If  $(b_{i,j})$  is a symmetric  $n \times n$  matrix all of whose coefficients satisfy the inequality  $|b_{i,j} - c_{i,j}| < \varepsilon$  then

$$\left|\sum_{i=1}^n\sum_{j=1}^n(b_{i,j}-c_{i,j})h_ih_j\right|<\varepsilon n^2=A,$$

for all  $(h_1, h_2, \ldots, h_n) \in S^{n-1}$ , hence

$$\sum_{i=1}^{n} \sum_{j=1}^{n} b_{i,j} h_i h_j > \sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j} h_i h_j - A \ge 0$$

for all  $(h_1, h_2, \ldots, h_n) \in S^{n-1}$ . Thus the matrix  $(b_{i,j})$  is positive definite, as required.

Using the fact that a symmetric  $n \times n$  matrix  $(c_{i,j})$  is negative definite if and only if the matrix  $(-c_{i,j})$  is positive definite, we see that if  $(c_{i,j})$  is a negative definite matrix then there exists some  $\varepsilon > 0$  with the following property: if all of the components of a symmetric  $n \times n$  matrix  $(b_{i,j})$  satisfy the inequality  $|b_{i,j} - c_{i,j}| < \varepsilon$ then the matrix  $(b_{i,j})$  is negative definite. Let  $f: X \to \mathbb{R}$  be a twice continuously differentiable real-valued function defined over some open set X in  $\mathbb{R}^n$ , and let **p** be a point of the open set X. We have already observed that if the function f has a local maximum or a local minimum at **p** then

$$\left. \frac{\partial f}{\partial x_i} \right|_{\mathbf{x}=\mathbf{p}} = 0 \qquad (i = 1, 2, \dots, n).$$

#### 9. Second Order Partial Derivatives and the Hessian Matrix (continued)

We now study the behaviour of the function f around a point  $\mathbf{p}$  at which the first order partial derivatives vanish. We consider the Hessian matrix  $(H_{i,i}(\mathbf{p}))$  defined by

$$H_{i,j}(\mathbf{p}) = \left. \frac{\partial^2 f}{\partial x_i \partial x_j} \right|_{\mathbf{x}=\mathbf{p}}$$

#### Lemma 9.5

Let  $f: X \to \mathbb{R}$  be a twice continuously differentiable real-valued function defined over an open set X in  $\mathbb{R}^n$ , and let **p** be a point of the open set X at which

$$\left. \frac{\partial f}{\partial x_i} \right|_{\mathbf{x}=\mathbf{p}} = 0 \qquad (i = 1, 2, \dots, n).$$

If f has a local minimum at the point **p** then the Hessian matrix  $(H_{i,j}(\mathbf{p}))$  at **p** is positive semi-definite.

## Proof

The first order partial derivatives of f are zero at  $\mathbf{p}$ . It follows that, given any vector  $\mathbf{h} \in \mathbb{R}^n$  which is sufficiently close to  $\mathbf{0}$ , there exists some  $\theta$  satisfying  $\mathbf{0} < \theta < 1$  (where  $\theta$  depends on  $\mathbf{h}$ ) such that

$$f(\mathbf{p}+\mathbf{h}) = f(\mathbf{p}) + \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n}h_{i}h_{j}H_{i,j}(\mathbf{p}+\theta\mathbf{h}),$$

where

$$H_{i,j}(\mathbf{p}+\theta\mathbf{h}) = \left.\frac{\partial^2 f}{\partial x_i \partial x_j}\right|_{\mathbf{x}=\mathbf{p}+\theta\mathbf{h}}$$

(see Proposition 9.3).

## It follows from this result that

$$\sum_{i=1}^n \sum_{j=1}^n h_i h_j H_{i,j}(\mathbf{p}) = \lim_{t \to 0} \frac{2(f(\mathbf{p}+t\mathbf{h})-f(\mathbf{p}))}{t^2} \ge 0.$$

The result follows.

Let  $f: X \to \mathbb{R}$  be a twice continuously differentiable real-valued function defined over some open set in  $\mathbb{R}^n$ , and let **p** be a point of the domain of f at which the first order partial derivatives of f are zero. The above lemma shows that if the function f has a local minimum at **p** then the Hessian matrix of f is positive semi-definite at **p**. However the fact that the Hessian matrix of fis positive semi-definite at **p** is not sufficient to ensure that f is has a local minimum at **p**, as the following example shows.

## Example

Consider the function  $f: \mathbb{R}^2 \to \mathbb{R}$  defined by  $f(x, y) = x^2 - y^3$ . The first order partial derivatives of f are zero at (0, 0). The Hessian matrix of f at (0, 0) is the matrix

$$\left(\begin{array}{cc} 2 & 0 \\ 0 & 0 \end{array}\right)$$

This matrix is positive semi-definite. However (0,0) is not a local minimum of f because f(0,y) < f(0,0) for all y > 0.

The following theorem shows that if the Hessian matrix of the function f is positive definite at a point at which the first order partial derivatives of f vanish then f has a local minimum at that point.

## Theorem 9.6

Let  $f: X \to \mathbb{R}$  be a twice continuously differentiable real-valued function defined over some open set X in  $\mathbb{R}^n$ , and let **p** be a point of X at which

$$\left. \frac{\partial f}{\partial x_i} \right|_{\mathbf{x}=\mathbf{p}} = 0 \qquad (i = 1, 2, \dots, n).$$

Suppose that the Hessian matrix  $(H_{i,j}(\mathbf{p}))$  of the function f at the point  $\mathbf{p}$  is positive definite. Then f has a local minimum at  $\mathbf{p}$ .

## Proof

The first order partial derivatives of f take the value zero at  $\mathbf{p}$ . It follows that, given any vector  $\mathbf{h}$  in  $\mathbb{R}^n$  which is sufficiently close to  $\mathbf{0}$ , there exists some  $\theta$  satisfying  $0 < \theta < 1$  (where  $\theta$  depends on  $\mathbf{h}$ ) such that

$$f(\mathbf{p}+\mathbf{h}) = f(\mathbf{p}) + \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n}h_{i}h_{j}H_{i,j}(\mathbf{p}+\theta\mathbf{h}),$$

where

$$H_{i,j}(\mathbf{p}+\theta\mathbf{h}) = \left.\frac{\partial^2 f}{\partial x_i \partial x_j}\right|_{\mathbf{x}=\mathbf{p}+\theta\mathbf{h}}$$

(see Proposition 9.3). Suppose that the Hessian matrix  $(H_{i,j}(\mathbf{p}))$  is positive definite. Then there exists some positive real number  $\varepsilon$  small enough to ensure that if  $|H_{i,j}(\mathbf{x}) - H_{i,j}(\mathbf{p})| < \varepsilon$  for all *i* and *j* then  $(H_{i,j}(\mathbf{x}))$  is positive definite (see Lemma 9.4).

But it follows from the continuity of the second order partial derivatives of f that there exists some positive real number  $\delta$  small enough to ensure that  $\mathbf{x} \in X$  and  $|H_{i,j}(\mathbf{x}) - H_{i,j}(\mathbf{p})| < \varepsilon$  for all integers i and j between 1 and n whenever  $|\mathbf{x} - \mathbf{p}| < \delta$ . Thus if  $0 < |\mathbf{h}| < \delta$  then  $(H_{i,j}(\mathbf{p} + \theta \mathbf{h}))$  is positive definite for all  $\theta \in (0, 1)$  so that  $f(\mathbf{p} + \mathbf{h}) > f(\mathbf{p})$ . Thus  $\mathbf{p}$  is a local minimum of the function f.

A symmetric  $n \times n$  matrix C is positive definite if and only if all its eigenvalues are strictly positive. In particular if n = 2 and if  $\lambda_1$  and  $\lambda_2$  are the eigenvalues of a symmetric  $2 \times 2$  matrix C, then

$$\lambda_1 + \lambda_2 = \operatorname{trace} C, \qquad \lambda_1 \lambda_2 = \det C.$$

Thus a symmetric  $2 \times 2$  matrix *C* is positive definite if and only if its trace and determinant are both positive.

## Example

Consider the function  $f: \mathbb{R}^2 \to \mathbb{R}$  defined by

$$f(x, y) = 4x^{2} + 3y^{2} - 2xy - x^{3} - x^{2}y - y^{3}.$$

Now

$$\left. \frac{\partial f(x,y)}{\partial x} \right|_{(x,y)=(0,0)} = 0 \quad \text{and} \quad \left. \frac{\partial f(x,y)}{\partial y} \right|_{(x,y)=(0,0)} = 0.$$

The Hessian matrix of f at (0,0) is

$$\left(\begin{array}{rrr} 8 & -2 \\ -2 & 6 \end{array}\right).$$

The trace and determinant of this matrix are 14 and 44 respectively. Hence this matrix is positive definite. We conclude from Theorem 9.6 that the function f has a local minimum at (0,0).
