Inferring Queue State by Measuring Delay in a WiFi Network

David Malone, Douglas J Leith, Ian Dangerfield

11 May 2009

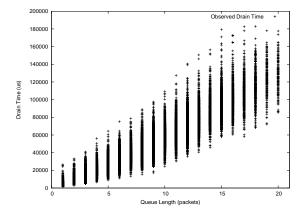

Wifi, Delay, Queue Length and Congestion Control

- RTT a proxy for queue length.
- Not too crazy in wired networks.
- For Wifi? Counting Down (20us) Someone else transmits, stop counting! Data and then ACK Collision followed by timeout
- With fixed traffic, what is impact of random service?
- What is impact of variable traffic (not even sharing buffer)?
- What will Vegas do in practice?
- Want to understand these for future design work.

Sample Previous work

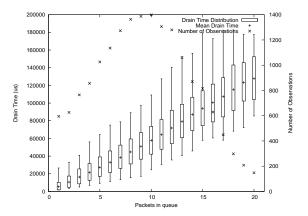

- V. Jacobson. pathchar a tool to infer characteristics of internet paths. MSRI, April 1997.

- M Franceschinis, M Mellia, M Meo, and M Munafo.
 Measuring TCP over WiFi: A real case. WiNMee, April 2005.
- G. McCullagh. Exploring delay-based tcp congestion control. Masters Thesis, 2008.

Fixed Traffic: How bad is the problem?

◆ロ ▶ ◆屈 ▶ ◆臣 ▶ ◆臣 ▶ ○臣 ○ のへで

What do the stats look like?

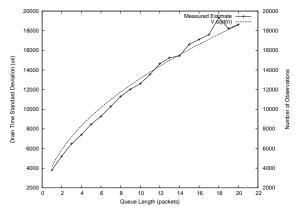

< ロ > < 同 > < 回 > < 回 >

э

Note: the variance is getting bigger.

How does it grow?

For fixed traffic service time looks uncorrelated.

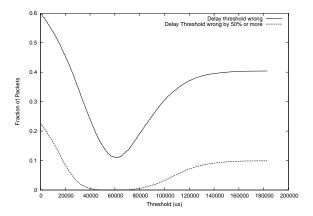

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

Queue Length Prediction

◆□▶ ◆□▶ ◆三▶ ◆三▶ → 三 ◆○へ⊙

- Suppose traffic is fixed.
- We have collect all statistics.
- Given an RTT, can we guess how full queue is?
- Easier: more or less than half full?

Results of thresholding

Using History

- Mistake 10% of time, not good for congestion control.
- Only using one sample, what happens if we use history.

◆□▶ ◆□▶ ◆三▶ ◆三▶ → 三 ◆○へ⊙

• Obvious thing to do: filter.

Filters

7/8 Filter

$$srtt \leftarrow 7/8srtt + 1/8rtt.$$

Exponential Time

srtt
$$\leftarrow e^{-\Delta T/T_c}$$
 srtt + $(1 - e^{-\Delta T/T_c})$ rtt.

Windowed Mean

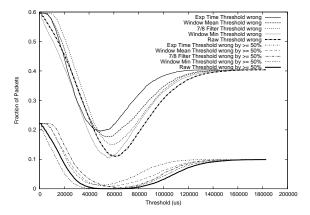

$$\operatorname{srtt} \leftarrow \operatorname{mean}_{\operatorname{last RTT}} \operatorname{rtt}.$$

Windowed Min

srtt
$$\leftarrow \min_{\text{last RTT}} \text{rtt.}$$

◆□▶ ◆□▶ ◆ □▶ ★ □▶ = = - のへぐ

How much better do we do?

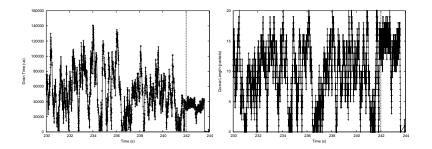

◆□ > ◆□ > ◆豆 > ◆豆 > ・豆 - のへぐ

Variable Network Conditions

- Other traffic can change service rate.
- Need not even share same buffer.
- Nonlinear because of collisions.
- What happens when we add/remove competing stations?

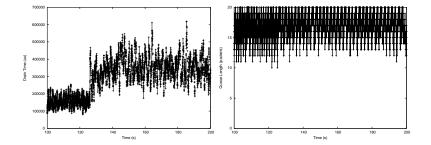

A D M A

Removing stations $(4 \rightarrow 1)$

(ロト (四) (三) (三) (三) (三) (0)

Adding stations $(4 \rightarrow 8, ACK Prio)$

(日)

Even base RTT changes.

Vegas in Practice

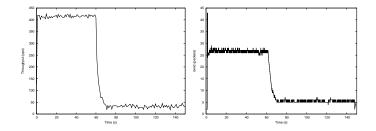

$TargetCwnd = cwnd \times baseRTT/minRTT$

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Make decision based on TargetCwnd - cwnd.

- Will Vegas make right decisions based on current RTT?
- Will Vegas get correct base RTT?
- Vary delay with dummynet.
- Vary BW by adding competing stations.

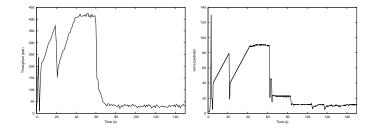

Vegas with 5ms RTT

◆□ > ◆□ > ◆豆 > ◆豆 > 「豆 」 のへで

Lower bound like $1 - \alpha / \text{cwnd}$.

Vegas with 200ms RTT

э

<ロ> <問> <問> < 回> < 回>

Sees loss and goes into Reno mode.

Conclusion

- With fixed traffic, delay is quite variable.
- Variability grows with buffer occupancy like \sqrt{n} .
- Obvious filters make things worse.
- Need to deal with change in traffic conditions.
- Linux Vegas does OK.
- Switch to Reno helps.
- Vegas insensitive at smaller buffer sizes.
- Variability at larger buffer sizes still a problem.
