1 Why does DL work?
2 How to quantify the learning capability of a DNN?
3 How does DL manipulate the probability distributions?
Why does DL work?
Deep learning is the mainstream technique for many machine learning tasks, including image recognition, machine translation, speech recognition, and so on. Despite its success, the theoretical understanding on how it works remains primitive.
Manifold Assumption

We believe the great success of deep learning can be partially explained by the well accepted manifold assumption and the clustering assumption:

**Manifold Assumption**

Natural high dimensional data concentrates close to a non-linear low-dimensional manifold.

**Clustering Assumption**

The distances among the probability distributions of subclasses on the manifold are far enough to discriminate them.

Deep learning method can learn and represent the manifold structure, and transform the probability distributions.
General Model

- Ambient Space - image space $\mathbb{R}^n$
- manifold - Support of a distribution $\mu$
- parameter domain - latent space $\mathbb{R}^m$
- coordinates map $\varphi_i$ - encoding/decoding maps
- $\varphi_{ij}$ controls the probability measure
Definition (Manifold)

Suppose $M$ is a topological space, covered by a set of open sets $M \subset \bigcup_{\alpha} U_{\alpha}$. For each open set $U_{\alpha}$, there is a homeomorphism $\varphi_{\alpha} : U_{\alpha} \rightarrow \mathbb{R}^n$, the pair $(U_{\alpha}, \varphi_{\alpha})$ form a chart. The union of charts form an atlas $\mathcal{A} = \{(U_{\alpha}, \varphi_{\alpha})\}$. If $U_{\alpha} \cap U_{\beta} \neq \emptyset$, then the chart transition map is given by

$$\varphi_{\alpha\beta} : \varphi_{\alpha}(U_{\alpha} \cap U_{\beta}) \rightarrow \varphi_{\beta}(U_{\alpha} \cap U_{\beta}),$$

$$\varphi_{\alpha\beta} := \varphi_{\beta} \circ \varphi_{\alpha}^{-1}.$$
Image space $\mathcal{X}$ is $\mathbb{R}^3$; the data manifold $\Sigma$ is the happy buddha.
The encoding map is $\varphi_i : \Sigma \rightarrow \mathcal{L}$; the decoding map is $\varphi_i^{-1} : \mathcal{L} \rightarrow \Sigma$. 
The automorphism of the latent space $\varphi_{ij} : \mathcal{L} \rightarrow \mathcal{L}$ is the chart transition.
Uniform distribution \( \zeta \) on the latent space \( \mathcal{Z} \), non-uniform distribution on \( \Sigma \) produced by a decoding map.
Uniform distribution $\zeta$ on the latent space $\mathcal{Z}$, uniform distribution on $\Sigma$ produced by another decoding map.
One facial image is determined by a finite number of genes, lighting conditions, camera parameters, therefore all facial images form a manifold.
Manifold view of Generative Model

Given a parametric representation $\varphi : \mathcal{X} \rightarrow \Sigma$, randomly generate a parameter $z \in \mathcal{X}$ (white noise), $\varphi(z) \in \Sigma$ is a human facial image.
Suppose $\tilde{p}$ is a point close to the manifold, $p \in \Sigma$ is the closest point of $\tilde{p}$. The projection $\tilde{p} \rightarrow p$ can be treated as denoising.
$\Sigma$ is the clean facial image manifold; noisy image $\tilde{p}$ is a point close to $\Sigma$; the closest point $p \in \Sigma$ is the resulting denoised image.
Manifold view of Denoising

Traditional Method
Fourier transform the noisy image, filter out the high frequency component, inverse Fourier transform back to the denoised image.

ML Method
Use the clean facial images to train the neural network, obtain a representation of the manifold. Project the noisy image to the manifold, the projection point is the denoised image.

Key Difference
Traditional method is independent of the content of the image; ML method heavily depends on the content of the image. The prior knowledge is encoded by the manifold.
If the wrong manifold is chosen, the denoising result is of non-sense. Here we use the cat face manifold to denoise a human face image, the result looks like a cat face.
How dose DL learn a manifold?
The central tasks for Deep Learning are

1. Learn the manifold structure from the data;
2. Represent the manifold implicitly or explicitly.
Figure: Auto-encoder architecture.

Ambient space $\mathcal{X}$, latent space $\mathcal{L}$, encoding map $\varphi_{\theta} : \mathcal{X} \rightarrow \mathcal{L}$, decoding map $\psi_{\theta} : \mathcal{L} \rightarrow \mathcal{X}$. 
The encoder takes a sample $x \in \mathcal{X}$ and maps it to $z \in \mathcal{F}$, $z = \varphi(x)$. The decoder $\psi : \mathcal{F} \to \mathcal{X}$ maps $z$ to the reconstruction $\tilde{x}$.

\[
\begin{align*}
\{(\mathcal{X}, x), \mu, M\} & \xrightarrow{\varphi} \{(\mathcal{F}, z), D\} \\
\psi \circ \varphi & \quad \psi \\
\{(\mathcal{X}, \tilde{x}), \tilde{M}\}
\end{align*}
\]

An autoencoder is trained to minimise reconstruction errors:

$$\varphi, \psi = \arg\min_{\varphi, \psi} \int_{\mathcal{X}} \mathcal{L}(x, \psi \circ \varphi(x)) d\mu(x),$$

where $\mathcal{L}(\cdot, \cdot)$ is the loss function, such as squared errors. The reconstructed manifold $\tilde{M} = \psi \circ \varphi(M)$ is used as an approximation of $M$. 

David Gu  Geometric Understanding
ReLU DNN

Definition (ReLU DNN)

For any number of hidden layers \( k \in \mathbb{N} \), input and output dimensions \( w_0, w_{k+1} \in \mathbb{N} \), a \( \mathbb{R}^{w_0} \rightarrow \mathbb{R}^{w_{k+1}} \) ReLU DNN is given by specifying a sequence of \( k \) natural numbers \( w_1, w_2, \ldots, w_k \) representing widths of the hidden layers, a set of \( k \) affine transformations \( T_i : \mathbb{R}^{w_{i-1}} \rightarrow \mathbb{R}^{w_i} \) for \( i = 1, \ldots, k \) and a linear transformation \( T_{k+1} : \mathbb{R}^{w_k} \rightarrow \mathbb{R}^{w_{k+1}} \) corresponding to weights of hidden layers.

The mapping \( \varphi_\theta : \mathbb{R}^{w_0} \rightarrow \mathbb{R}^{w_{k+1}} \) represented by this ReLU DNN is

\[
\varphi = T_{k+1} \circ \sigma \circ T_k \circ \cdots \circ T_2 \circ \sigma \circ T_1,
\]

where \( \circ \) denotes mapping composition, \( \theta \) represent all the weight and bias parameters.
Fix the encoding map $\varphi_\theta$, let the set of all neurons in the network is denoted as $\mathcal{I}$, all the subsets is denoted as $2^\mathcal{I}$.

**Definition (Activated Path)**

Given a point $\mathbf{x} \in \mathcal{X}$, the *activated path* of $\mathbf{x}$ consists all the activated neurons when $\varphi_\theta(\mathbf{x})$ is evaluated, and denoted as $\rho(\mathbf{x})$. Then the activated path defines a set-valued function $\rho : \mathcal{X} \rightarrow 2^\mathcal{I}$. 

David Gu

Geometric Understanding
Definition (Cell Decomposition)

Fix a encoding map $\phi_\theta$ represented by a ReLU RNN, two data points $x_1, x_2 \in \mathcal{X}$ are equivalent, denoted as $x_1 \sim x_2$, if they share the same activated path, $\rho(x_1) = \rho(x_2)$. Then each equivalence relation partitions the ambient space $\mathcal{X}$ into cells,

$$\mathcal{D}(\phi_\theta) : \mathcal{X} = \bigcup_{\alpha} U_\alpha,$$

each equivalence class corresponds to a cell: $x_1, x_2 \in U_\alpha$ if and only if $x_1 \sim x_2$. $\mathcal{D}(\phi_\theta)$ is called the cell decomposition induced by the encoding map $\phi_\theta$.

Furthermore, $\phi_\theta$ maps the cell decomposition in the ambient space $\mathcal{D}(\phi_\theta)$ to a cell decomposition in the latent space.
Encoding/Decoding

Figure: Auto-encoder pipeline.

- a. Input manifold $M \subset \mathcal{X}$
- b. Latent representation $D = \varphi_\theta(M)$
- c. Reconstructed manifold $\tilde{M} = \psi_\theta(D)$
Piecewise linear encoding/decoding maps induce cell decompositions of the ambient space and the latent space.
Definition (Rectified Linear Complexity of a ReLU DNN)

Given a ReLU DNN $N(w_0, \ldots, w_{k+1})$, its rectified linear complexity is the upper bound of the number of pieces of all PL functions $\varphi_\theta$ represented by $N$,

$$\mathcal{N}(N) := \max_\theta \mathcal{N}(\varphi_\theta).$$

Rectified Linear complexity gives a measurement for the representation capability of a neural network.
Lemma

The maximum number of parts one can get when cutting $d$-dimensional space $\mathbb{R}^d$ with $n$ hyperplanes is denoted as $C(d, n)$, then

$$C(d, n) = \binom{n}{0} + \binom{n}{1} + \binom{n}{2} + \cdots + \binom{n}{d}. \quad (2)$$

Proof.

Suppose $n$ hyperplanes cut $\mathbb{R}^d$ into $C(d, n)$ cells, each cell is a convex polyhedron. The $(n+1)$-th hyperplane is $\pi$, then the first $n$ hyperplanes intersection $\pi$ and partition $\pi$ into $C(d - 1, n)$ cells, each cell on $\pi$ partitions a polyhedron in $\mathbb{R}^d$ into 2 cells, hence we get the formula

$$C(d, n+1) = C(d, n) + C(d - 1, n).$$
Theorem (Rectified Linear Complexity of a ReLU DNN)

Given a ReLU DNN $N(w_0, \ldots, w_{k+1})$, representing PL mappings $\varphi_\theta : \mathbb{R}^{w_0} \rightarrow \mathbb{R}^{w_{k+1}}$ with $k$ hidden layers of widths $\{w_i\}_{i=1}^k$, then the linear rectified complexity of $N$ has an upper bound,

$$\mathcal{N}(N) \leq \prod_{i=1}^{k+1} \mathcal{C}(w_{i-1}, w_i).$$  \hspace{1cm} (3)
Definition (Linear Rectifiable Manifold)

Suppose $M$ is a $m$-dimensional manifold, embedded in $\mathbb{R}^n$, we say $M$ is linear rectifiable, if there exists an affine map $\varphi : \mathbb{R}^n \to \mathbb{R}^m$, such that the restriction of $\varphi$ on $M$, $\varphi|_M : M \to \varphi(M) \subset \mathbb{R}^m$, is homeomorphic. $\varphi$ is called the corresponding rectified linear map of $M$. 

a. linear rectifiable b. non-linear-rectifiable
Definition (Linear Rectifiable Atlas)

Suppose $M$ is a $m$-dimensional manifold, embedded in $\mathbb{R}^n$, $\mathcal{A} = \{(U_\alpha, \varphi_\alpha)\}$ is an atlas of $M$. If each chart $(U_\alpha, \varphi_\alpha)$ is linear rectifiable, $\varphi_\alpha : U_\alpha \to \mathbb{R}^m$ is the rectified linear map of $U_\alpha$, then the atlas is called a linear rectifiable atlas of $M$.

Definition (Rectified Linear Complexity of a Manifold)

Suppose $M$ is a $m$-dimensional manifold embedded in $\mathbb{R}^n$, the rectified linear complexity of $M$ is denoted as $\mathcal{N}(\mathbb{R}^n, M)$ and defined as,

$$
\mathcal{N}(\mathbb{R}^n, M) := \min \{|\mathcal{A}| \mid \mathcal{A} \text{ is a linear rectifiable atlas of } M\}.
$$

(4)
**Definition (Encoding Map)**

Suppose $M$ is a $m$-dimensional manifold, embedded in $\mathbb{R}^n$, a continuous mapping $\varphi : \mathbb{R}^n \to \mathbb{R}^m$ is called an encoding map of $(\mathbb{R}^n, M)$, if restricted on $M$, $\varphi|_M : M \to \varphi(M) \subset \mathbb{R}^m$ is homeomorphic.

**Theorem (Encodable Condition)**

Suppose a ReLU DNN $N(w_0, \ldots, w_{k+1})$ represents a PL mapping $\varphi_\theta : \mathbb{R}^n \to \mathbb{R}^m$, $M$ is a $m$-dimensional manifold embedded in $\mathbb{R}^n$. If $\varphi_\theta$ is an encoding mapping of $(\mathbb{R}^n, M)$, then the rectified linear complexity of $N$ is no less that the rectified linear complexity of $(\mathbb{R}^n, M)$,

$$\mathcal{N}(\mathbb{R}^n, M) \leq \mathcal{N}(\varphi_\theta) \leq \mathcal{N}(N).$$
Lemma

Suppose a $n$ dimensional manifold $M$ is embedded in $\mathbb{R}^{n+1}$,

\[ M \xrightarrow{G} S^n \xrightarrow{p} \mathbb{RP}^n \]

where $G : M \to S^n$ is the Gauss map, $\mathbb{RP}^n$ is the real projective space, if $p \circ G(M)$ covers the whole $\mathbb{RP}^n$, then $M$ is not linear rectifiable.
Representation Limitation Theorem

Theorem

Given any ReLU deep neural network $N(w_0, w_1, \ldots, w_k, w_{k+1})$, there is a manifold $M$ embedded in $\mathbb{R}^{w_0}$, such that $M$ cannot be encoded by $N$.
How does DL control the probability distribution?
A generative model converts a white noise into a facial image.
The analogy that is often used here is that the generator is like a forger trying to produce some counterfeit material, and the discriminator is like the police trying to detect the forged items.
GAN Overview

**Merits**

1. Automatic generate samples, the requirement for the data samples is reduced;
2. Data sample distribution can be arbitrary, without closed form expression.
GAN Overview

Figure: GAN DNN model.

Figure: GAN learning process.
Wasserstein GAN Model

$\mathcal{X}$-image space; $\Sigma$-supporting manifold; $\mathcal{Z}$-latent space;

$G: g_\theta$,

$D: W_c(\mu_\theta, \nu), \varphi_\xi$
ν-training data distribution; ζ-uniform distribution; 
μ_θ = g_θζ-generated distribution; G - generator computes g_θ; 
D - discriminator, measures the distance between ν and μ_θ, 
W_c(μ_θ, ν).
$G : \mathcal{Z} \rightarrow \mathcal{X}$ maps a fixed probability distribution $\zeta$ to the training data probability distribution $\nu$. 

Noise $\sim N(0,1)$
Overview

Wasserstein Space

Given a Riemannian manifold $M$, all the probability distributions on $M$ form an infinite dimensional manifold Wasserstein space $\mathcal{W}(M)$, the distance between two probability distributions is given by the so-called Wasserstein distance.

Optimal Mass Transportation

Given two probability measures $\mu, \nu \in \mathcal{W}(M)$, there is a unique optimal mass transportation map $T : M \rightarrow M$, $\varphi$ maps $\mu$ to $\nu$ with the minimal transportation cost. The transportation cost of the optimal transportation map is the Wasserstein distance between $\mu$ and $\nu$. 
Definition (Measure-Preserving Mapping)

Given two bounded domains in $\mathbb{R}^n$ with probability measures $(X, \mu)$ and $(Y, \nu)$, with equal total measure $\mu(X) = \nu(Y)$, a transportation mapping $T : X \to Y$ is measure-preserving, if for any measurable set $B \subset Y$,

$$\int_{T^{-1}(B)} d\mu(x) = \int_B d\nu(y),$$

and denoted as $T_#\mu = \nu$.

Suppose $T$ is a smooth map, then measure-preserving condition is equivalent to the Jacobian equation

$$\mu(x) dx = \nu(y) dy$$

$$det(DT) = \frac{\mu(x)}{\nu \circ T(x)}.$$
Definition (Transportation Cost)

Suppose the cost of moving a unit mass from point $x$ to point $y$ is $c(x, y)$, for a transportation map $T : (X, \mu) \rightarrow (Y, \nu)$, the total transportation cost is

$$C(T) = \int_X c(x, T(x)) d\mu(x).$$

$$(X, \mu) \quad (Y, \nu)$$

$T$
The cost of moving a unit mass from point $x$ to point $y$.

$\text{Monge}(1781) : c(x, y) = |x - y|.$

This is the natural cost function. Other cost functions include

\[
\begin{align*}
c(x, y) &= |x - y|^p, p \neq 0 \\
c(x, y) &= -\log |x - y| \\
c(x, y) &= \sqrt{\varepsilon + |x - y|^2}, \varepsilon > 0
\end{align*}
\]

Any function can be cost function. It can be negative.
Monge Problem

Problem (Monge)

Find a measure-preserving transportation map 
\( T : (X, \mu) \rightarrow (Y, \mu) \) that minimizes the transportation cost,

\[
(MP) \quad \min_{T_\# \mu = \nu} \mathcal{C}(T) = \min_{T_\# \mu = \nu} \int_X c(x, T(x)) d\mu(x).
\]

such kind of map is called the optimal mass transportation map.

Definition (Wasserstein distance)

The transportation cost of the optimal transportation map 
\( T : (X, \mu) \rightarrow (Y, \nu) \) is called the Wasserstein distance between \( \mu \) and \( \nu \), denoted as

\[
W_c(\mu, \nu) := \min_{T_\# \mu = \nu} \mathcal{C}(T).
\]
Kantorovich relaxed transportation maps to transportation schemes.

Problem (Kantorovich)

Find an optimal transportation scheme, namely a joint probability measure \( \rho \in \mathcal{P}(X \times Y) \), with marginal measures \( \rho_{x\#} = \mu, \rho_{y\#} = \nu \), that minimizes the transportation cost,

\[
(KP) \quad \min_{\rho} \left\{ \int_{X \times Y} c(x, y) d\rho(x, y) \big| \rho_{x\#} = \mu, \rho_{y\#} = \nu \right\}.
\]

Kantorovich solved this problem by inventing linear programming, and won Nobel’s prize in economics in 1975.
By the duality of linear programming, Kantorovich problem has the dual form:

**Problem (Kantorovich Dual)**

*Find an functions $\phi : X \to \mathbb{R}$ and $\psi : Y \to \mathbb{R}$, such that*

$$
(DP) \max_{\phi, \psi} \left\{ \int_X \phi(x) du(x) + \int_Y \psi(y) dv(y), \phi(x) + \psi(y) \leq c(x, y) \right\}.
$$
**Kantorovich Dual Problem**

**Definition (c-transformation)**

Given a function $\phi : X \to \mathbb{R}$, and $c(x, y) : X \times Y \to \mathbb{R}$, its c-transform $\phi^c : Y \to \mathbb{R}$ is given by

$$\phi^c(y) := \inf_{x \in X} \{c(x, y) - \phi(x)\}.$$

**Problem (Kantorovich Dual)**

The Kantorovich Dual problem can be reformulated as

$$\max_{\phi} \left\{ \int_X \phi(x) \, du(x) + \int_Y \phi^c(y) \, dv(y) \right\}.$$ 

$\phi$ is called Kantorovich potential.
Wasserstein GAN Model

$v$-training data distribution; $\zeta$-uniform distribution; $\mu_\theta = g_\theta \# \zeta$-generated distribution; $G$ - generator computes $g_\theta$; $D$ - discriminator, measures the distance between $v$ and $\mu_\theta$, $W_c(\mu_\theta, v)$. 

David Gu

Geometric Understanding
From the optimal transportation point of view, Wasserstein GAN performs the following tasks:

- The discriminator: computes the Wasserstein distance using Kantorovich Dual formula:

  \[ W_c(\mu_\theta, \nu) = \max_{\varphi_\xi} \int_X \varphi_\xi(x) d\mu_\theta(x) + \int_Y \varphi_\xi^c(y) d\nu(y), \]

  namely computes the Kantorovich potential \( \varphi \);

- The generator: computes a measure-preserving transportation map \( g_\theta : X \to X' \), s.t. \( g_\theta \# \zeta = \mu_\theta = \nu \).

- The WGAN model: min-max optimization

  \[ \min_{\theta} \max_{\zeta} \int_X \varphi_\xi \circ g_\theta(z) d\zeta(z) + \int_Y \varphi_\xi^c(y) d\nu(y) \]
When $c(x, y) = |x - y|$, $\varphi_c = -\varphi$, given $\varphi$ is 1-Lipsitz, the WGAN model: min-max optimization

$$\min_{\theta} \max_{\xi} \int_{X} \varphi_{\xi} \circ g_{\theta}(z) d\zeta(z) - \int_{Y} \varphi_{\xi}(y) d\nu(y).$$

namely

$$\min_{\theta} \max_{\xi} \mathbb{E}_{z \sim \zeta}(\varphi_{\xi} \circ g_{\theta}(z)) - \mathbb{E}_{y \sim \nu}(\varphi_{\xi}(y)).$$

with the constraint that $\varphi_{\xi}$ is 1-Lipsitz.
Brenier’s Approach

Theorem (Brenier)

If \( \mu, \nu > 0 \) and \( X \) is convex, and the cost function is quadratic distance,

\[
c(x, y) = |x - y|^2
\]

then there exists a convex function \( u : X \rightarrow \mathbb{R} \) unique upto a constant, such that the unique optimal transportation map is given by the gradient map

\[
T : x \rightarrow \nabla u(x).
\]

Problem (Brenier)

Find a convex function \( u : X \rightarrow \mathbb{R} \), such that

\[(BP) \quad (\nabla u)_\# \mu = \nu,\]

\( u \) is called the Brenier potential.
From Jacobian equation, one can get the necessary condition for Brenier potential.

**Problem (Brenier)**

Find the Brenier potential $u : X \rightarrow \mathbb{R}$ satisfies the Monge-Ampere equation

$$(BP) \quad det \left( \frac{\partial^2 u}{\partial x_i \partial x_j} \right) = \frac{\mu(x)}{v(\nabla f(x))}.$$
Theorem

If the distance function \( c(x, y) = h(x - y) \), where \( h : \mathbb{R} \rightarrow \mathbb{R} \) is a strictly convex function, the Kantorovich potential \( \phi : X \rightarrow \mathbb{R} \) gives the optimal mass transportation map directly:

\[
T(x) = x - (\nabla \phi)^{-1}(\nabla \phi(x))
\]

Corollary

Suppose \( c(x, y) = \frac{1}{2}|x - y|^2 \), then Kantorovich potential and Brenier potential satisfy the relation

\[
u(x) = \frac{1}{2}|x|^2 - \phi(x).
\]
The discriminator computes the Kantorovich potential $\varphi$; the generator $G$ computes the optimal transportation map, $T = \nabla u$, where $u$ is the Brenier potential; The Brenier potential equals to

$$u = \frac{1}{2} |x|^2 - \varphi(x).$$

Hence, in theory:
- $G$ can be obtained from the optimal $D$ without training;
- $D$ can be obtained from the optimal $G$ without training;
- The two deep neural networks are redundant;
- The competition between $D$ and $G$ is unnecessary.
In practice, the target probability measure is approximated by empirical distribution:

\[ v = \sum_{i=1}^{n} \delta(y - y_i)v_i, \]

in general \( v_i = 1/n. \)
Given a compact convex domain $\Omega$ in $\mathbb{R}^n$ and $p_1, \cdots, p_k$ in $\mathbb{R}^n$ and $A_1, \cdots, A_k > 0$, find a transport map $T : U \rightarrow \{p_1, \cdots, p_k\}$ with $\text{vol}(T^{-1}(p_i)) = A_i$, so that $T$ minimizes the transport cost

$$\frac{1}{2} \int_{U} |x - T(x)|^2 \, dx.$$
∀y_i ∈ Y, construct a hyper-plane π^i_h(x) = ⟨x, y_i⟩ − h_i;
compute the upper envelope of the planes 
u_h(x) = \max_i\{\pi^i_h(x)\}
produce the power diagram of Ω, \mathcal{V}(h) = \bigcup_i W_i(h);
adjust the heights h, such that µ(W_i(h)) = ν_i.
Figure: Variation of the $\mu$-volume of top-dimensional cells.

Adjust the height of each hyper-plane, such that $\mu(W_i(h)) = v_i$. 
Convex Geometry
Example

A convex polygon $P$ in $\mathbb{R}^2$ is determined by its edge lengths $A_i$ and the unit normal vectors $n_i$.

Take any $u \in \mathbb{R}^2$ and project $P$ to $u$, then $\langle \sum_i A_i n_i, u \rangle = 0$, therefore

$$\sum_i A_i n_i = 0.$$
Minkowski Problem

Given $k$ unit vectors $\mathbf{n}_1, \cdots, \mathbf{n}_k$ not contained in a half-space in $\mathbb{R}^n$ and $A_1, \cdots, A_k > 0$, such that

$$\sum_i A_i \mathbf{n}_i = 0,$$

find a compact convex polytope $P$ with exactly $k$ codimension-1 faces $F_1, \cdots, F_k$, such that

1. $\text{area}(F_i) = A_i$,
2. $\mathbf{n}_i \perp F_i$. 
Theorem (Minkowski)

$P$ exists and is unique up to translations.
Theorem (Brunn-Minkowski)

For every pair of nonempty compact subsets \( A \) and \( B \) of \( \mathbb{R}^n \) and every \( 0 \leq t \leq 1 \),

\[
[\text{Vol}(tA \oplus (1-t)B)]^{\frac{1}{n}} \geq t[\text{vol}(A)]^{\frac{1}{n}} + (1-t)[\text{vol}(B)]^{\frac{1}{n}}.
\]

For convex sets \( A \) and \( B \), the inequality is strict for \( 0 < t < 1 \) unless \( A \) and \( B \) are homothetic i.e. are equal up to translation and dilation.
Theorem (Alexandrov 1950)

Given $\Omega$ compact convex domain in $\mathbb{R}^n$, $p_1, \cdots, p_k$ distinct in $\mathbb{R}^n$, $A_1, \cdots, A_k > 0$, such that $\sum A_i = \text{Vol}(\Omega)$, there exists PL convex function

$$f(\mathbf{x}) := \max\{\langle \mathbf{x}, \mathbf{p}_i \rangle + h_i | i = 1, \cdots, k\}$$

unique up to translation such that

$$\text{Vol}(W_i) = \text{Vol}(\{\mathbf{x} | \nabla f(\mathbf{x}) = \mathbf{p}_i\}) = A_i.$$

Alexandrov’s proof is topological, not variational. It has been open for years to find a constructive proof.
**Theorem (Gu-Luo-Sun-Yau 2013)**

Ω is a compact convex domain in \( \mathbb{R}^n \), \( y_1, \ldots, y_k \) distinct in \( \mathbb{R}^n \), \( \mu \) a positive continuous measure on \( \Omega \). For any \( \nu_1, \ldots, \nu_k > 0 \) with \( \sum \nu_i = \mu(\Omega) \), there exists a vector \((h_1, \ldots, h_k)\) so that

\[
    u(x) = \max \{ \langle x, p_i \rangle + h_i \}
\]

satisfies \( \mu(W_i \cap \Omega) = \nu_i \), where \( W_i = \{ x \mid \nabla f(x) = p_i \} \).

Furthermore, \( h \) is the maximum point of the convex function

\[
    E(h) = \sum_{i=1}^{k} \nu_i h_i - \int_{0}^{h} \sum_{i=1}^{k} w_i(\eta) \, d\eta_i,
\]

where \( w_i(\eta) = \mu(W_i(\eta) \cap \Omega) \) is the \( \mu \)-volume of the cell.

Accepted by Asian Journal of Mathematics (AJM)
One can define a cylinder through $\partial \Omega$, the cylinder is truncated by the xy-plane and the convex polyhedron. The energy term $\int^h \sum w_i(\eta) d\eta_i$ equals to the volume of the truncated cylinder.
Definition (Alexandrov Potential)

The concave energy is

\[ E(h_1, h_2, \ldots, h_k) = \sum_{i=1}^{k} v_i h_i - \int_{0}^{h} \sum_{j=1}^{k} w_j(\eta) d\eta_j, \]

Geometrically, the energy is the volume beneath the parabola.
The gradient of the Alexanrov potential is the differences between the target measure and the current measure of each cell

$$\nabla E(h_1, h_2, \cdots, h_k) = (\nu_1 - w_1, \nu_2 - w_2, \cdots, \nu_k - w_k)$$
The Hessian of the energy is the length ratios of edge and dual edges,

\[
\frac{\partial w_i}{\partial h_j} = \frac{|e_{ij}|}{|\bar{e}_{ij}|}
\]
Generative Model
Use autoencoder to realize encoder and decoder, use OMT in the latent space to realize probability transformation.
